SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

WEDNESDAY, OCTOBER 2, 1985

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
TASK FORCE ON SCIENCE POLICY,
Washington, DC.

The task force met pursuant to call at 9:30 a.m., in room 2318, Rayburn House Office Building, Hon. Don Fuqua (chairman of the task force) presiding.

Mr. FUQUA. Today is the first of 6 days of hearings on the topic "Science in the Mission Agencies and Federal Laboratories." These are the last of the scheduled hearings of the Science Policy Task Force for 1985.

Our Federal Government supports science not only through science agencies, such as the National Science Foundation, but also through mission agencies, such as the Departments of Defense, Agriculture and Energy, and the National Aeronautics and Space Administration. The mission agencies, the science agencies, and the regulatory agencies also perform research in their own laboratories. The purpose of these hearings is to examine their significant contribution to the U.S. research base.

These hearings will focus on five issues: first, coordination and management of Federal research programs; second, mission agency relationships with extramural research performers; third, the role of the mission agencies in the science and engineering infrastructure; fourth, regulation-driven research; and fifth, the role of the Federal laboratories.

During these 6 days of hearings, which will conclude October 24, we will hear from many distinguished witnesses. Some of them will represent mission or regulatory agencies, or the Federal laboratories. Others will speak as performers of research for the agencies or laboratories; and still others as advisors or independent experts.

In addition, we have also requested the Congressional Research Service to provide a comprehensive study of the role of the Department of Defense in providing support for scientific research. A draft will be provided to the witnesses for comments.

Today's hearing is divided into two parts. First, we have a panel overview of Science in the Mission Agencies and Federal Laboratories. Then we will hear a second panel of Defense Department research policymakers. And our final witness is a former Under Secretary of Defense for Research and Engineering who is now a private consultant.

PANEL 1: OVERVIEW OF SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

Mr. FUQUA. Let me now call panel No. 1. Our first witness is Dr. Albert H. Teich, head of the office of public sector programs of the American Association for the Advancement of Science. Our second witness is Dr. W. Henry Lambright, professor of political science and public administration at the Maxwell School of Syracuse University.

These two gentlemen have collaborated on a number of papers about the Federal laboratories and the Federal Government's organization for science and have written independently on these topics as well. Welcome gentlemen. We are very happy to hear from you. Dr. Teich, we will be pleased to hear from you at this time.

[A biographical sketch of Dr. Teich follows:]

DR. ALBERT H. TEICH

Albert H. Teich is Head of the Office of Public Sector Programs at the American Association for the Advancement of Science. This office is reponsible for AAAS activities in public policy and public understanding of science and technology. From 1980 through mid-1984, he served as manager of science policy studies at AAAS, heading the R&D Budget and Policy Project and serving as staff officer for the Committee on Science, Engineering and Public Policy. In 1980–1981, he directed a major AAAS project in support of the National Science Foundation's preparation of the second *Five-Year Outlook for Science and Technology*. Prior to joining AAAS, Dr. Teich was associate professor of public affairs and deputy director of the Graduate Program in Science, Technology and Public Policy at George Washington University. Between 1969 and 1976, he served in a number of research, administrative, and teaching positions at Syracuse University Research Corporation and the State University of New York, including director of research of SUNY's Institute for Public Policy Alternatives in Albany. He has been a consultant to many organizations and federal agencies, including the National Science Foundation, the National Academy of Sciences, and the House Committee on Science and Technology. Dr. Teich is the author of many articles and the editor of three books, *Scientists and Public Affairs* (MIT Press, 1974), *Technology and Man's Future*, 3rd ed. (St. Martin's Press, 1981), and *Science, Technology and the Issues of the Eighties: Policy Outlook* (Westview Press, 1982). He holds a B.S. in physics and a Ph.D. in political science, both from M.I.T.

STATEMENT OF DR. ALBERT H. TEICH, HEAD, OFFICE OF PUBLIC SECTOR PROGRAMS, AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, WASHINGTON, DC

Dr. TEICH. Thank you, Mr. Chairman. It is a privilege for me to present this testimony to you at your hearings today. I have followed the work of the task force over the past several months, and I believe it can have a major impact on the source of science policy in this country. I am honored to have an opportunity to contribute to its work.

As head of the office of public sector programs at the AAAS, I devoted a great deal of my time and effort to the issue of science policy, particularly issues associated with Federal R&D. I should emphasize that, however, that I am presenting this testimony as an individual and views that I will express are my own, and should not be taken as representing positions of the AAAS.

Mr. Chairman, I have submitted my written statement for the record, and with your permission, I would like to summarize its main points.

Mr. FUQUA. We will make all of the statements today part of the record, and if you wish to summarize, please feel free to do so.

Dr. TEICH. Good. My purpose in this statement is to provide an overview of research in the mission agencies, a bit of historical context and some observations on trends and policy issues that need to be addressed and I hope this will set the stage for the task force's work over the next several days.

By mission agencies, I mean those Federal agencies which support research but whose primary purpose is not to support research itself, but rather pursuit of broader societal purposes. More than 30 agencies of the Federal Government support research. Most of these are mission agencies. In fact in general usage, only two of these agencies are considered nonmission or science agencies, NSF and NIH.

The distinction, however, is not a precise one. Well, of the two nonmission agencies, NSF is clearly a science agency. Its main purpose is support of bank research, as you know, across a broad spectrum of scientific and engineering fields. NIH is also classified as a science agency and certainly is one at least from the point of view of biomedical research communities, which sees its fundamental purpose of support basically on medical research from other points of view. NIH is also a mission agency whose mission is advancement of the Nation's health and improvement of medical practice, and that has served mainly through research.

On the other hand, although the Department of Energy is, of course, regarded as a mission agency, its program of general science and research is in many respects a science agency within the Department. It supports programs, the most basic kind of research, high energy physics, and operates in a manner that is quite different from the rest of the Department with little relation to DOE's energy mission.

Despite these ambiguities, the concepts of mission and nonmission agencies do make intuitive sense. And I think they are useful in understanding some important aspects of science policy.

Let me mention two empirical ways of distinguishing between mission and nonmission agencies that may be of help to you in these hearings. The first is the relative importance of research in the overall picture of the agency as reflected in its budget. That is the agency's research intensiveness. In my prepared statement, I have included a table which shows the total budget and the research expenditures and the ratios between the two. The table shows that 91 percent of the NSF budget and the 1984 budget of NIH budget went to research. That is table 1, which appears at the end of the statement. None of the mission agencies devote more than about 40 percent of their budgets to research, and most of them devote much less. For example, the Department of Transportation and Department of Education devote less than 1 percent of their overall budgets to research.

TABLE 1.—OVERALL BUDGET, RESEARCH AND R&D FUNDING LEVEL BY AGENCY, FISCAL YEAR 1984

[Budget authority, millions of dollars]

	Overall budget	R&D	Research	R&D as percent of overall budget	Research as percent of overall budget
Agriculture	$31,235	$871	$839	2.8	2.7
Commerce	2,016	358	294	17.8	14.6
Defense-military	258,150	27,337	3,055	10.6	1.2
Education	15,423	101	78	.7	.5
Energy	10,539	4,528	1,864	43.0	17.7
HHS	299,428	4,828	4,457	1.6	1.5
(NIH)	(4,494)	(4,253)	(3,906)	(94.6)	(86.9)
Interior	4,917	358	335	7.3	6.8
Transportation	28,594	465	69	1.6	.2
AID	1,316	192	139	14.6	10.6
EPA	4,064	260	173	6.4	4.3
NASA	7,316	2,822	1,709	38.6	23.3
NRC	466	191	191	41.0	41.0
NSF	1,328	1,203	1,203	90.6	90.6
VA	26,477	193	174	.7	.7

NOTE: Includes all agencies with more than $100 million in R&D. Figures for R&D and research are for conduct only; facilities are not included.

Source: Office of Management and Budget.

That is one way of looking at the difference between mission and nonmission agencies. The other way, the other empirical way of distinguishing between them, I owe to my friend, Henry Lambright, and has to do with style of research administration in the two types of agencies. Dr. Lambright, in a book called, "Governing Science and Technology," characterizes agencies as "science-oriented or society-oriented" and points out the difference between the two styles of research administration that one finds in those two agencies. For example, science-oriented agencies support research while society-oriented agencies purchase it. He notes that science-oriented agencies employ unsolicited proposals, peer reviewed by scientists and funded through grants, while society-oriented agencies tend to work through solicitations and review proposals internally and fund projects under contracts. He also notes that science-oriented agencies emphasize excellence as a criterion for funding and allow researchers to operate with considerable autonomy, whereas society-oriented agencies emphasize relevance and are more concerned about accountability and responsiveness to their own needs. There are a couple of other differences, some noted in my statement, and others described more fully in Professor Lambright's book.

But these, of course, are not pure types. Most agencies reflect a mix, often with differences between their subunits. In fact, these differences, as I have described them, are a little bit of characterizations, but they do capture the different ties well-known to anyone who has dealt with Federal R&D.

Let me turn now very briefly to a history of mission agency research. Probably the most important point is that the history of science in the Federal Government is mostly that of the mission agencies. The science agencies, NSF and NIH, are in fact, in the long view, relatively recent additions to the scene. A good source of in-

formation on that history, which I will not review in detail, is the National Science Board's report, "Basic Research in the Mission Agencies" published in 1978, which I know has been utilized by the task force in preparing for these hearings.

The rise of science in the mission agencies begins in the early days of the Republic with surveys and explorations funded by various Federal agencies. Systemic research closer to what we know now today began to grow in the Agriculture Department through the Hatch Act, which set up the land grant colleges of the Civil War era and later in the 19th century. Other mission agency research began early in this century with the Bureau of Standards and the work of Bureau of Mines, and subsequently the National Advisory Committee on Aeronautics—which, of course, was later transformed into the NASA, the space agency.

Interestingly, this Nation saw relatively little need to support military research except during war time, and even when the Naval Research Laboratory was set up after World War I, it was given relatively little money. Of course, the Second World War and experience with science and technology in that context changed all of this, and in its aftermath arose a new role for the Federal Government in support of basic research.

The centerpiece of this new Federal role was the National Science Foundation, which came about as a result of a recommendation in the Bush report, "Science: The Endless Frontier." But this centerpiece was actually quite a small component of Federal research support since the mission agencies grew quite rapidly during the post-war period. Rather than taking over support of research in the post-war environment, NSF began to be viewed as more of a "balance wheel," filling in where needed among the programs of other agencies.

On the current scene, the mission agencies continue to play dominant roles in many areas of research. In table 2, in my statement, I have calculated the percentage distribution by agencies of Federal funds for the major disciplines of research for fiscal year 1984, including both basic and applied research. The results are quite eye-opening to someone who hasn't thought or looked at these figures. The mission agencies really dominate most areas of research. The Defense Department, for example, provided nearly 23 percent of all Federal funding for physical science research, 50 percent of Federal funding for math and computer science research, and almost a third of Federal support for psychology. NASA and DOE also support large shares of physical science and environmental science and engineering research. NSF shares are smaller. In fact, in only one area, environmental sciences, does NSF support the largest single share of research, and here its portion is over one-fourth.

TABLE 2.—PERCENTAGE DISTRIBUTION OF RESEARCH BY AGENCY FOR MAJOR FIELDS OF SCIENCE, FISCAL YEAR 1984

[Based on estimated obligations]

	Total	Life sciences	Psych.	Phys. sciences	Envir. sciences	Math/ computers	Engin.	Social sciences	Other
Agriculture	5.6	10.2	[1]	2.3	1.1	2.9	1.5	21.8	.....

The numbers are somewhat different if one focuses only on basic research instead of basic and applied, which I have just done. Those figures are shown in a separate table, table 3, with the overall message the same. Mission agencies provide a larger share of Federal support for most science fields. The only major exception to that is in the life sciences where a single agency—NIH—supports by far the largest share of research in biological and medical sciences, 75 percent. In many ways this seems to be a special case.

Where the science agencies are most important, and the role of the mission agencies is consequently least evident, is in overall support of basic research at universities and colleges contained in table 4 in my statement. As that table shows, nearly three-fourths, 73 percent, of federally funded basic research at colleges and universities is funded by the two science agencies, NIH and NSF. Nearly half in fact is supported by NIH alone.

Most of the mission agencies contribute relatively smaller shares to overall support of academic basic research—Agriculture, about 3½ percent, Energy, about 5, Defense 11, NASA, 4 percent, and all off the others less than 1 percent each. On the other hand, because mission agencies tend to concentrate their support in limited numbers of areas, their support is more important in universities and colleges in those specific fields. For example, the Agriculture Department, of course, is most active and most important in universi-

ties' agricultural research as you will hear later on during these hearings.

Well, my observations of current policy environments suggest a number of trends and issues bearing on research in the mission agencies that I believe merit the task force's attention. Let me mention briefly five of these.

The first has to do with funding levels. The Reagan administration's science policies have had mixed effects on research in the mission agencies. Despite a period of austerity on the civilian side of the budget, the administration, with the support of the Congress, has gained substantial increases for basic research during the past four years. The science agencies—NSF and NIH—have done particularly well, but DOE, NASA, DOD have also recorded real growth in their basic research programs during this period. Table 5 presents the figures in current dollars, not including the effects of inflation.

TABLE 5.—FEDERAL FUNDING FOR RESEARCH AND BASIC RESEARCH BY AGENCY, FISCAL YEAR 1981 AND FISCAL YEAR 1985

[Obligations in millions of dollars]

	Basic research			Research		
	Fiscal year 1981	Fiscal year 1985	Percent change	Fiscal year 1981	Fiscal year 1985	Percent change

Source: National Science Foundation.

At the same time, the administration has sought to reduce fund for applied research, development and demonstration programs in the nondefense agencies on the grounds that such efforts are more appropriate for the private sector. The reductions in applied research programs have been substantial in a number of agencies, including DOE's civilian programs, the National Oceanic and Atmospheric Administration—NOAA—in the Department of Commerce, Interior, and EPA.

These countervailing trends present several concerns. One, first of all, is that the distinction between basic and applied research is not all that clearcut, and thus these changes may not necessarily produce the intended effects. For example, reductions in NOAA's applied research programs may have significant negative impacts

on what many regard as basic research in atmospheric sciences and oceanography.

Apart from this, the increase in basic research has been based largely on the belief that it will contribute to economic growth and national security. Without disputing this belief, one might argue that it is equally important for the Federal Government to support generic applied research efforts as a means of facilitating the utilization of basic knowledge in practical applications. Thus, current policies on basic and applied research may actually be working against one another.

Finally, the reductions in applied research programs may be having negative impacts on institutions—Federal laboratories, university research centers, et cetera—that are affecting their ability to conduct basic research.

The proposed establishment of a Department of Science, as you know, this issue, which is kind of perennial, has arisen again in the past few months, and I don't wish to get involved in a discussion of the pros and cons of that proposal. My prepared statement summarizes a few of them, but I do want to simply point out that the issues having to do with the departmental proposal are deeply involved with research in the mission agencies. And I would also want to voice my concerns that the impacts on the mission agencies, the potential impacts that might result from creation of such a department have to be weighed if this topic gets debated seriously. I don't think they have received much attention in the discussions of the department.

My third point has to do with priorities among fields. I would mention that because of the way in which research budgets are disbursed among the mission agencies. The key priority decisions in research are made in the context of several different agency budgets, with relatively little opportunities for cross-comparisons on the basis of criteria related to science. In other words, basic research in agriculture competes mainly with other agricultural priorities while high energy physics competes not so much with other areas of science, but with energy programs.

The only executive branch units really capable of taking an overview of the basic research system, the Office of Management and Budget and the Office of Science and Technology Policy, affect it mainly at the margins. The diffusion of responsibility for basic research in the Congress means that even if the administration should prepare a budget with carefully weighted choices among fields of science, it would not be likely to receive a coherent legislative review.

Nonetheless, it is worth asking whether the present allocations are optimal, either in terms of the needs of the scientific community or the potential applications to which the research might eventually be put. There may not be a scientific way to answer the question of whether biomedical research and high energy physics merit their current levels of support relative to, say, materials science or anthropology, but raising the questions may still be a useful contribution to the political process through which resources for research in both the mission and nonmission agencies are allocated.

My fourth point has to do with the responsibility of the mission agencies for the research infrastructure. Over the past several years, it has become apparent that the infrastructure of U.S. science requires more attention than it has been receiving. The state of science education at all levels, the obsolescence of scientific instrumentation in universities, the condition of academic laboratories and other facilities, the participation of minorities, women, and other under-represented groups have all been the subject of study and discussion. All need to be addressed through action.

The problem of facilities, in particular, has given rise to several instances in which universities have sought to obtain funds through direct intervention in the legislative process, bypassing traditional peer review procedures. In the past, mission agencies played a significant role in the supporting university research facilities, through such efforts as NASA's Sustaining University Program and DOD's Centers of Excellence Program. The continued importance of research in the mission agencies to U.S. science, as discussed earlier in this statement, dictates that solutions to infrastructure problems must involve the mission agencies in more than a token manner. The Committee on Science and Technology is aware of this and the recent legislation on university facilities—H.R. 2823, Universities Research Facilities Revitalization Act of 1985—introduced by the chairman deserves support and encouragement.

Research management in the mission agencies. The discussion of differences between science-oriented and society-oriented research administration which I presented earlier in this statement suggests some of the continuing tensions which face mission agency research at the operational level. In general, these tensions stem from the researchers' desire for autonomy in their work to pursue the most promising and rewarding avenues from a scientific standpoint, versus the agencies' need to direct the research into areas most relevant to their missions. When managed creatively, these tensions can help stimulate extremely productive work, as is the case in some of the Nation's best industrial laboratories. But, when the tensions are manifested in rigid bureaucracies and increasingly confining regulations, the results are antithetical to the conduct of good research.

This is not a new issue, but as I have tried to show, research in the mission agencies is not a new phenomenon. That research is a source of continuing strength for U.S. science and technology and the conditions that help it to flourish need continuing attention. That is why these hearings are so important.

Thank you, Mr. Chairman. That concludes my statement, and I will be happy to answer questions.

[The prepared statement of Dr. Teich follows:]

Statement of

Dr. Albert H. Teich

Head, Office of Public Sector Programs

American Association for the Advancement of Science

Washington, D.C.

before the

Task Force on Science Policy

Committee on Science and Technology

U. S. House of Representatives

Hearings on Science in the Mission Agencies and Federal Laboratories

2318 Rayburn House Office Building

Washington, D.C.

October 2, 1985

Mr. Chairman and Members of the Task Force:

It is a privilege for me to present this testimony to you at your hearings on research in the mission agencies and national laboratories. I have followed the work of the Task Force over the past several months and I believe it can have a major impact on the course of science policy in this nation. I am honored to have an opportunity to contribute to its work.

As head of the Office of Public Sector Programs of the American Association for the Advancement of Science (AAAS), I devote much of my tim and effort to issues of science policy, particularly policy and administrative issues associated with federal research and development programs. I should note, however, that I am presenting this testimony as an individual. The views I will express are my own and should not be taken as representing positions of the AAAS.

I. INTRODUCTION

A major portion of federally-funded research is supported by agencies whose primary purpose is not support of science but rather the pursuit of broader societal purposes. These "mission agencies," as they are termed in science policy discussions, include such diverse entities as the Department of Defense, the Environmental Protection Agency and the Department of Commerce. In general, research is supported by these agencies not for the sake of advancing knowledge (although this is certainly a known and desired outcome), but rather as a means of contributing to the achievement of the agency's goals. At the same

time, this research plays a key role in the support and advancement of U.S. science and engineering. My purpose in this statement is to provide an overview of research in these mission agencies, a bit of historical context, and some observations on trends and policy issues that need to be addressed. I hope this will help set the stage for the Task Force's consideration of this important topic over the next several days.

II. WHAT ARE THE MISSION AGENCIES AND WHAT DISTINGUISHES THEM FROM NON-MISSION AGENCIES?

More than thirty agencies of the federal government support research and development activities. In general usage, only two of these agencies are considered non-mission or science agencies -- the National Science Foundation (NSF) and the National Institutes of Health (NIH). All of the others (with the possible exception of the Smithsonian) are termed mission agencies.

In the case of NSF the distinction is significant and relatively straightforward. NSF's main purpose is the support of basic research (mainly but not exclusively in universities and colleges) across a broad spectrum of scientific and engineering disciplines. For the others, however, the line between mission and non-mission is not all that clear.

NIH, for example, is certainly a science agency from the point of view of the biomedical research community which sees its fundamental purpose as the support of basic biomedical research. The Institutes operate with considerable autonomy, support a great deal of university

research, and even conduct their in-house programs much in the style of academic institutions. From the point of view of many policymakers, medical care practitioners, and interest groups, however, NIH is a mission agency whose mission -- the advancement of the nation's health and the improvement of medical practice — is served mainly through research. Furthermore, NIH, despite its considerable operational autonomy, is not a freestanding agency but an administrative unit of the Public Health Service (PHS). The PHS, in turn, is a part of the Department of Health and Human Services (DHHS), a huge department with a broad and important mission in which research is only a small element.

Similarly, the program of General Science and Research in the Department of Energy (DOE) is in many respects a science agency within its department. It suports perhaps the most basic of all basic research, high energy physics, through a program often described as a "national trust," which operates in a manner quite different from the rest of the department and has little relation to DOE's energy mission.

These ambiguities aside, the concepts of mission and non-mission agencies do make intuitive sense and, as these hearings will no doubt show, are useful in understanding some important aspects of science policy.

Perhaps the most direct way of distinguishing between mission and non-mission agencies is in the relative importance of research to the agency, as reflected in its budget — i.e., the agency's research intensiveness. Table 1 displays the overall budgets, research and R&D

funding levels, and the ratios of research and R&D funding to overall budget for the major federal research agencies in fiscal year 1984. These measures are similar to R&D as a percent of sales, a metric commonly used in comparing industrial firms and sectors.

Here the differences between the science agencies — NSF and NIH, with ratios of research to total budget of 91 and 87 percent, respectively — and the mission agencies are clearly evident. It is easy to understand how research in NSF and NIH, where it is practically the agencies' exclusive function, is treated differently than that in the mission agencies. It is also apparent that mission agencies differ substantially among themselves in the share of their resources devoted to research. For example, the Department of Transportation spends only 0.2 percent of its budget on research, while NASA spends nearly a quarter of its total funding on research (and nearly 40 percent on R&D). These differences can be seen in comparing the administrative orientations of mission and non-mission agencies.

As Lambright noted a number of years ago, research administration in NSF and NIH can be characterized as "science-oriented," while that in the mission agencies is "society-oriented."(1) Among the differences between the two styles are the following:

- Science-oriented agencies <u>support</u> research; society-oriented agencies <u>purchase</u> it.

- Science-oriented agencies employ unsolicited proposals, peer reviewed by scientists and funded through grants; society-

oriented agencies prefer to work through solicitations, review proposals internally and fund projects under contracts.

- o Administrators in science-oriented agencies view extramural researchers as "colleagues"; society-oriented administrators see them as "performers."

- o Science-oriented agencies emphasize excellence as a criterion for funding and allow researchers to operate with considerable autonomy; society-oriented agencies emphasize relevance and are more concerned about accountability and responsiveness to their own needs.

These are not, of course, pure types. Most agencies reflect a mix, often with differences among subunits. Nonetheless, as indications of central tendencies in administration the differences are real. The predominant mode in NSF and NIH is certainly "science-oriented" in these terms, while that in other agencies is -- with occasional exceptions -- "society-oriented."

III. HISTORICAL PERSPECTIVE

Mission agency research has a long and distinguished history in the United States. In fact, several of the mission agencies were supporting research long before the science agencies came into existence. The history of science in the federal government prior to World War II is almost entirely that of the mission agencies. In this statement I will only mention a few of the highlights of that history. Excellent

historical reviews are contained in several books and the National Science Board's extensive and detailed report, Basic Research in the Mission Agencies, published in 1978. (2)

Prior to the Civil War most governmental uses of science and engineering research were relatively small scale and ad hoc in nature. The federal government sponsored a considerable amount of exploration and mapping, as well as, a number of Coast and Geodetic Surveys (functions now conducted by the National Ocean Survey in the Department of Commerce). The Army Corps of Engineers and U.S. Military Academy were established early in the 1800s; the Smithsonian was created (through the bequest of a foreigner) during that period; and there were several attempts (none successful) to create a national university.

Federal funding of agricultural research in land grant colleges and state agricultural experiment stations had its origins in the Morrill and Hatch Acts of the Civil War era and late nineteenth century, and the National Academy of Sciences was established during this period as well. Research on basic standards and related problems, growing out of the need to standardize weights and measures for commerce, began with the creation of the National Bureau of Standards early in the twentieth century. And in the same period, mining research programs developed in the Bureau of Mines. The National Advisory Committee on Aeronautics (NACA), the forerunner of NASA, was established in 1915 and was followed some years later by the establishment of the National Institute (now Institutes) of Health. Military research became

institutionalized after World War I, with the creation of the National Research Council (NRC) in association with the National Academy of Sciences. The NRC was intended to coordinate the work of scientists outside the government with that of government. A permanent Naval Research Laboratory was also established after the war although -- as was the case with other peacetime military research prior to World War II -- funding was at a rather low level.

Mission agency research, like virtually all other governmental activity, was much smaller in absolute terms in the pre-World War II era. One estimate is that the whole federal R&D budget in 1939 was only $50 million.(3) Although statistics are not readily available, it is probably fair to say that mission agency research in those days was also smaller relative to other government activties than it is now -- i.e., the agencies were less research intensive -- and performance of research was more heavily intramural.

World War II was a great watershed for U.S. science and technology. The dramatic demonstration of the power of organized research and development to yield practical results of unprecedented importance, including of course the atomic bomb, completely changed the scale, direction and course of science and technology in the federal government and the nation as a whole. Of primary importance was the acceptance, marked by the Bush Report, Science -- The Endless Frontier, of a major federal role in the support of basic research.

The proposed creation of a new federal science agency -- a National Research Foundation, later the National Science Foundation -- was

central to the new federal role. But the Foundation's position was never intended to be an exclusive one. The mission agencies were to retain their applied research activities, while the new agency was to support basic research across all fields in a manner unhindered by demands for near-term results.(4) Later, as the postwar structure evolved and basic research programs became institutionalized in many of the mission agencies, a different concept developed for NSF. The Foundation, whose funding level was quite small relative to other federal research agencies -- in FY 1960, NSF represented less than 1 percent of federal R&D funding -- began to be viewed as a "balance wheel," filling in where needed among the programs of the other agencies.

Research in the mission agencies grew rapidly in the postwar years with defense leading the way. The Defense Department, together with the weapons and other military-related research functions of the Atomic Energy Commission, dominated growth of federal R&D. In the late 1950s, in response to Sputnik, these agencies were joined by a rapidly growing National Aeronautics and Space Adminstration (NASA).

Health, environment and other nondefense areas began to receive increased emphasis in the late 1960s with the advent of the Great Society's social programs and the widespread political sentiment that the fruits of federal science and technology should be applied to pressing national needs. Expanding federal responsibilities in energy and environment, and new regulatory roles, combined with a slow-down in defense and space spending shifted the balance during the 1970s.

More recently, with a new spurt of growth in military spending and austerity in nondefense programs, the balance has begun to swing back in the other direction -- although funding for basic research (in particular in NSF and NIH) has fared quite well relative to many areas of government activity.

IV. CURRENT ROLE OF THE MISSION AGENCIES IN FEDERAL RESEARCH

On the current scene, the mission agencies continue to play dominant roles in many areas of research. Table 2 presents the percentage distribution by agency of federal funds in the major areas of research in FY 1984 (including both basic and applied research). As the table shows, the Defense Department provided nearly 23 percent of all federal funding for physical science research, 50 percent of federal funding for math and computer science research, and almost a third of federal support for psychology. NASA and DOE also support large shares of physical science, environmental science, and engineering research. NSF's shares are smaller. In only one area, environmental sciences, does it support the largest single share of research, and even here its portion is just over one-fourth.

The numbers are somewhat different if one focuses only on basic research, as shown in Table 3, but the overall message is the same: the mission agencies provide the largest share of federal support for most science fields. The only major exception to this is in the life sciences, where a single science agency, NIH, supports by far the largest share of research in biological and medical sciences (75 percent). In many ways, this seems a special case in science policy.

Where the science agencies are most important (and the role of the mission agencies consequently least evident) is in overall support of basic research at universities and colleges, as shown in Table 4. One half of the basic research supported by the federal government is performed at universities and colleges ($3.5 out of $6.9 billion in FY 1984, according to NSF figures). Of this amount, nearly three-fourths (73 percent) is funded by NIH and NSF, and nearly half (49 percent) by NIH alone.

Most of the mission agencies contribute relatively small shares to overall support of academic basic research: Agriculture, 3.5 percent; Energy, 4.9 percent; Defense, 11.3 percent; NASA 4.4 percent; all of the others, less than one percent each. On the other hand, because most of the mission agencies tend to concentrate their support in a limited number of areas, their support is more important in universities and colleges in those fields (e.g., the Department of Agriculture in agricultural research, the Department of Education in education, and NASA in astronomy). Furthermore, these figures do not include support of basic research in federally funded research and development centers (FFRDCs), such as Fermilab, which operate more or less as extensions of academia and are used heavily by academic scientists. This form of operation is particularly important in DOE support of high energy and nuclear physics.

V. TRENDS AND POLICY ISSUES

My observations of the current policy environment suggest a number of trends and issues bearing on research in the mission agencies that

merit the Task Force's attention. Some appear directly in the statement of purpose for these hearings; others underlie it, but are not mentioned explicitly.

A. Funding Levels

The Reagan Administration's science policies have had mixed effects on research in the mission agencies. Despite a period of austerity on the civilian side of the budget, the administration, with the support of the Congress, has gained substantial increases for basic research during the past four years. The science agencies -- NSF and NIH -- have done particularly well, but DOE, NASA and DOD have also recorded real growth in their basic research programs during this period. Table 5 presents the figures (in current dollars, not including the effects of inflation).

At the same time, the administration has sought to reduce funding for applied research, development and demonstration programs in the nondefense agencies on the grounds that such efforts are more appropriate for the private sector. The reductions in applied research programs have been substantial in a number of agencies, including DOE's civilian programs, the National Oceanic and Atmospheric Administration (NOAA) in the Department of Commerce, Interior, and EPA. (The figure for DOE in Table 5 includes nuclear weapons research as well as civilian energy technology.)

These countervailing trends present several concerns:

(1) First of all, the distinction between basic and applied research is not all that clear-cut, and thus these changes may not necessarily produce the intended effects. For example, reductions in NOAA's applied research programs may have significant negative impacts on what many regard as basic research in atmospheric sciences and oceanography. In addition, it seems likely that the administration's different approaches to support of basic and applied research have made the already arbitrary process of classifying these programs for budget reporting even more capricious.

(2) Apart from this, the increase in basic research has been based largely on the belief that it will contribute to economic growth and national security. Without disputing this belief, one might argue that it is equally important for the federal government to support generic applied research efforts as a means of facilitating the utilization of basic knowledge in practical applications. Thus, current policies on basic and applied research may actually be working against one another.

(3) Finally, the reductions in applied research programs may be having negative impacts on institutions (federal laboratories, university research centers, etc.) that are affecting their ability to conduct basic research.

B. Proposed Establishment of a Department of Science

During recent months the notion of establishing a cabinet-level department of science and technology, a seemingly-perennial issue in science policy, has surfaced once again, this time through a recommendation of the President's Commission on Industrial Competitiveness. Although the current version is not likely to gain approval in the near future, it is worth taking note of the issue here because it is closely related to the problems of research in the mission agencies.

Most proposals for creating a science department involve regrouping the R&D functions of various existing agencies. Central to the discussion, therefore, are the relative merits of the current decentralized system of responsibility for R&D, in which most of the mission agencies maintain their own research programs, compared with more centralized systems.

Presumed virtues of centralization include greater efficiency, eliminating duplication of effort, more "clout" for science (based on cabinet status and the ability to speak with a single voice), and (through the joining of science with technology) more rapid application of research results to societal purposes. On the other side of the ledger are (possibly) reducing the effectiveness of research and technology transfer by separating the research from the agency which might apply it; concerns over "placing all of one's eggs in a single basket" for budget purposes; diminished technical capabilities in the mission agencies whose R&D programs are transferred to the new

department; and (of particular concern to the academic science community) loss of the flexibility that comes with multiple points of access and redundancy in potential funding sources.

These pros and cons will bear considerable discussion should the Department of Science and Technology proposal gain serious consideration. The impacts on the mission agencies will need to be understood and treated in the debate.

C. Priorities Among Fields

The problem of setting priorities among fields in research is one that has long occupied the attention of science policymakers. Although a variety of systematic approaches has been proposed, the essential questions of how much to spend on, say, astronomy versus molecular biology are made in a political rather than a scientific manner.

Because of the way in which research budgets are dispersed among the mission agencies, the key priority decisions in research are made in the context of several different agency budgets, with relatively little opportunity for cross-comparisons on the basis of criteria related to science. Basic research in agriculture competes mainly with other agricultural priorities, while high energy physics competes not so much with other areas of science, but with energy programs.

The only Executive Branch units really capable of taking an overview of the basic research system — the Office of Management and Budget and

57-279 O - 87 - 2

the Office of Science and Technology Policy -- affect it mainly at the margins. The diffusion of responsibility for basic research in the Congress means that even if the administration should prepare a budget with carefully weighted choices among fields of science, it would not be likely to receive a coherent legislative review.

Nonetheless, it is worth asking whether the present allocations are optimal, either in terms of the needs of the scientific community or the potential applications to which the research might eventually be put. There may not be a "scientific" way to answer the question of whether biomedical research and high energy physics merit their current levels of support relative to, say, materials science or anthropology, but raising the questions may still be a useful contribution to the political process through which resources for research in both the mission and non-mission agencies are allocated.

D. Responsibility of the Mission Agencies for the Research Infrastructure

Over the past several years, it has become apparent that the infrastructure of U.S. science requires more attention than it has been receiving. The state of science education at all levels, the obsolescence of scientific instrumentation in universities, the condition of academic laboratories and other facilities, the participation of minorities, women and other under-represented groups have all been the subject of study and discussion. All need to be addressed through action.

The problem of facilities, in particular, has given rise to several instances in which universities have sought to obtain funds through

direct intervention in the legislative process, bypassing traditional peer review procedures. In the past, mission agencies played a significant role in the supporting university research facilities, through such efforts as NASA's Sustaining University Program and DOD's Centers of Excellence Program. The continued importance of research in the mission agencies to U.S. science (as discussed earlier in this statement) dictates that solutions to infrastructure problems must involve the mission agencies in more than a token manner. The Committee on Science and Technology is aware of this and the recent legislation on university facilities (HR 2823, Universities Research Facilities Revitalization Act of 1985) introduced by the Chairman deserves support and encouragement.

E. Research Management in the Mission Agencies

The discussion of differences between science-oriented and society-oriented research administration which I presented earlier in this statement suggests some of the continuing tensions which face mission agency research at the operational level. In general, these tensions stem from the researchers' desire for autonomy in their work to pursue the most promising and rewarding avenues from a scientific standpoint, versus the agencies' need to direct the research into areas most relevant to their missions. When managed creatively, these tensions can help stimulate extremely productive work, as is the case in some of the nation's best industrial laboratories. But, when the tensions are manifested in rigid bureaucracies and increasingly confining regulations, the results are antithetical to the conduct of good research.

This is not a new issue, but as I have tried to show, research in the mission agencies is not a new phenomenon. That research is a source of continuing strength for U.S. science and technology and the conditions that help it to flourish need continuing attention. That is why these hearings are so important.

Thank you.

Mr. FUQUA. Thank you.

We will hear from Dr. Lambright now, and then we will have some questions for the two of you.

[A biographical sketch of Dr. Lambright follows:]

DR. W. HENRY LAMBRIGHT

W. Henry Lambright is a professor of Political Science and Public Administration at the Maxwell School, Syracuse University, and director of the Science and Technology Policy Center at Syracuse Research Corporation. Dr. Lambright received his A.B. at Johns Hopkins in 1961, and his M.A. and Ph.D. at Columbia University in 1962 and 1966, respectively. After a year at the Brookings Institution, Dr. Lambright joined the faculty of Maxwell School where he has spent his academic career. He has served as a special assistant with NASA, and consulted for various Federal, State, and local agencies as well as private organizations. Dr. Lambright is a specialist in government as it relates to science, technology, and public policy. He is author of numerous articles and four books, *Governing Science and Technology, Technology Transfer to Cities: Processes of Choice at the Local Level, Educating the Innovative Public Manager,* and *Presidential Management of Science and Technology: The Johnson Presidency.*

STATEMENT OF DR. W. HENRY LAMBRIGHT, PROFESSOR, THE MAXWELL SCHOOL, SYRACUSE UNIVERSITY, AND DIRECTOR, SCIENCE AND TECHNOLOGY POLICY CENTER, SYRACUSE RESEARCH CORP., SYRACUSE, NY

Dr. LAMBRIGHT. Thank you. It is a pleasure to be here, and enjoy my friend Al Teich. Again, I am going to read certain portions of my testimony and summarize the remainder.

At the core of Federal science and technology policy are the Federal laboratories. These often ignored and frequently maligned institutions are one of a number of performers—universities and industry are the primary others—but they are unique in being of the Government. This is true whether they are civil service labs or Government-owned, contractor-operated. They are extensions of Government policy. As such, they provide a technical base of knowledge to the agencies that give them support. They help advise in setting Federal science and technology policies through their agency sponsors; and then they play a large role in implementing those policies as performers of research and development—R&D—and as managers of the work of universities and industry. These are institutions in the middle, and as one would expect of institutions in such a position, they are often subject to various cross-pressures.

Who governs the Federal laboratories? Who influences the direction and pace of their R&D programs? What are the current pressures on and within the laboratories? What are the trends? Where have they been? Where are they headed? In addressing these questions, we will be focusing on the policy issues.

Federal laboratories and Federal policies are supposed to go hand in hand. But sometimes they do not. Federal labs may be part of or extensions of Government, their dominant sponsor. But they also are semiautonomous, frequently as a matter of deliberate design by their creators. They have minds—or policies—of their own. Sometimes such policies are different from Federal policy. This may be good or it may be bad, but it is an inevitable consequence of the size, pluralism, and complexity of the American science and technology enterprise.

The Federal laboratory universe is both huge and diverse. There are more than 700 laboratories in the United States. As noted, these vary greatly in form. Over the years there have been numerous consolidations and even some closings.

A great deal of Federal R&D funds flow to these organizations—approximately one-third. The 1985 Department of Energy, DOE, funding to the 12 multiprogram labs alone was almost $4 billion.

These are usually large institutions, employing sometimes many thousands of people per lab. Oak Ridge National Laboratory, ORNL, alone has almost 5,000 employees, while Lawerence Livermore employs over 7,000. Collectively, the Federal laboratories employ nearly half a million scientists and engineers. Not only are they large in terms of employees, but the Federal laboratories house some of the most expensive and sophisticated scientific equipment in the world.

As to quality, it is natural that this large number includes everything from the outstanding to the mediocre. Among the stronger Federal labs are those that are called national labs. Exactly what makes a national lab different from a Federal laboratory has never been spelled out in any precise way. In the beginning of the 20th century, the National Bureau of Standards, NBS, was established and perhaps pioneered the model. That is, while located under a specific agency, this laboratory had a mission that went beyond that agency and reached to other agencies and the Nation at large. Today, we have many laboratories that have national in their titles: for example, Argonne National Laboratory; Los Alamos National Laboratory, LANL; and National Institutes of Health, NIH. But there are organizations that behave as national institutions which do not have this designation: for example, Jet Propulsion Laboratory, JPL.

The notion of the national laboratory is not just a matter of verbal ornamentation. It reflects a perception, held both inside and ouside the lab, that these institutions are national resources, rather than strictly agency resources. As Congress knows, what people think can be as important as what is where Federal policymaking is concerned. It can affect behavior and the relative independence of national laboratories as compared with other Federal laboratories. The relation of Federal laboratories to Government is somewhat open-ended. Government means other agencies, Congress, and the President. This is because those other institutions see these institutions as separable from agency sponsors—too important to be just the concerns of those agencies.

It is recognized that Federal laboratories, national and otherwise, are crucial to the implementation of U.S. science and technology policies. The fact that these hearings are taking place, in which the Federal labs are a focus of attention, underlines the point. These hearings are the latest of a sequence of studies of the Federal laboratories including one for the White House under David Packard. What is not so well recognized is the fact that these institutions have missions and roles that are self-generated as well as provided to them. Sometimes, the policy signals they get from Government—agency, Congress, President—differ or are slow to develop. Inevitably, there are differences in ends and means among the various players in Federal laboratory policy. Hence, continuity,

change, and conflict take place at different times in the relations between the lab and its policy environment.

In my prepared testimony, I discuss the evolution of the Federal labs in terms of six phases. First, the World II revolution in Federal science and technology policy, 1940–45; second, the atomic energy era, 1945–57; third, the space era, 1957–69; fourth, the era of uncertainty 1969–73; fifth, the energy era, 1973–81; and sixth, the second era of uncertainty, 1981 to the present. These phases bring out differences in emphasis in Federal civil science and technology policy. These represent the major policy shifts for the labs.

Suffice it to say here, in summary, that major labs were born of World War II, and grew after the war, and during the 1950's when atomic energy development was a priority. Other labs were added in the 1960's when space became a national technology mission. After a brief downturn, the shuttle decision and the energy crisis stained many of these newer labs and added to their growth in the 1970's.

I now skip most of the historical parts of the testimony and come to the present time. I will now focus on the contemporary period which I call a second period of uncertainty. This is on page 11 of my prepared testimony.

In 1981, the Reagan administration took office. This coincided with a sharp diminution of the energy threat from OPEC. The Reagan administration decided that energy was no longer a top priority in Federal science and technology. Indeed, the administration sought to dismantle DOE, only to be stopped by Congress. Significantly, however, there was no serious thought given to abandoning the national laboratories under DOE. These would be preserved in part because some of them—for example, LANL, Lawerence Livermore, and Sandia—were primarily weapons labs. Also, all the DOE labs had a great deal of political support and recognized merit independent of DOE. There could be sharp controversy about DOE, in part because of its regulatory responsibilities. But there is relative consensus about the importance of the labs. The big question for a while was where to put them, and one candidate was the Department of Commerce. Nevertheless, with the lessening of funding for energy, the civilian energy labs needed to ask about missions and roles again.

Missions have to do with energy, space, defense, or some other national problem. Role pertains to whether the labs have a place in a given field at all—or should it be the role of the university or industry to be engaged in a particular mission. The Reagan administration, more than any other in the history of labs, raised the question of role, and did so in a way as to narrow considerably what they had been doing. Specifically, it said that the role of the labs was to perform research that was relatively basic and long term, of a high risk character, and work that could not or would not be done by the private sector. This meant that the role of the labs in demonstrations and commercialization was curtailed dramatically, while that in basic research augmented. What the labs were supposed to do about technology development was unclear.

So, the civilian energy labs had a problem of diminished mission and narrowed role in the 1980's. Also, longstanding conflicts with industry and universities reemerged, given a smaller energy R&D

pie to divide. Ironically, the manned space labs of NASA were doing all right in the 1980's as the Reagan administration gave a priority to space R&D it withdrew from energy. The Shuttle was continued and the manned Space Station decision made. Hence, the space labs had relative stability in their environment in terms of mission and role.

The most significant development was with the Department of Defense, DOD. Its R&D funding was growing. This meant that both the NASA and DOE labs could try to obtain support from this source, and some of them did so to avoid layoffs. While manned space missions were doing relatively well, some of the unmanned science satellite programs were not. JPL, which saw some of its programs in this field diminish, looked toward DOD for bolstering.

It was one matter for the NASA labs to supplement their work through DOD, whose own space programs were growing. It was more difficult for the civilian energy laboratories to go in this direction. As a result, a number of the civilian energy labs are shrinking.

What has been happening has been a searching for new missions by the civilian energy labs. This search has been wide ranging, well beyond DOD. For example, ORNL has moved vigorously into disaster work for the Federal Emergency Management Agency and into international energy research for the Agency for International Development. But perhaps the most important, intriguing, and problematic new mission emphasis is economic development.

There is increasing recognition that international competition among high technology nations is creating serious new problems for the United States. The nature of national labs is to relate to national problems. There have been some seminal relationships established. For example, the White House Office of Science and Technology Policy was the principal advocate behind a new national laboratory-steel industry research program that is currently evolving. This is a partnership "in which the steel industry, two national laboratories of DOE, and the NBS are working together to develop 'leap frog' technology to help the steel industry achieve increases in productivity, meet foreign competition, and prepare for the 21st century." Science Advisor Keyworth has explained: "One practical result is to marry the technical expertise of the labs with the needs of the steel industry. The national labs will not do the steel companies' jobs for them; this program provides access for a threatened and important domestic industry to existing taxpayer-supported technical resources" (Alan Schriesheim, "Federal R&D Policy," *Science,* Vol. 226, Nov. 16, 1984; George Keyworth, "Science and Technology Policy: The Next Four Years," *Technology Review,* Feb./Mar. 1984, vol. 88, No. 2).

There is an enormous interest in economic development coming from various States and some local governments. As labs in the early 1970's sought to be relevant to problems of cities and other public service areas, so in the mid-1980's they are groping to find economic linkages with industry and universities at the regional level. It is a fact that in some areas Federal laboratories are the key technical resource. States see this, and are themselves seeking to facilitate relationships for economic development. One new rela-

tionship is taking place along the corridor between ORNL and Knoxville.

A major policy development relevant to lab-industry linkages, and thus economic development, has to do wth patent policies. For years, relations between labs and industry were inhibited by industry fears that Government would take patent property in inventions such relationships might have produced. Now there are changes taking place. For example, in 1980, Congress passed the Bayh-Dole Act, which granted small business firms and not-for-profit organizations greater opportunities to acquire patent rights for federally funded inventions; in 1985, Congress is considering extending the same principles to large business firms. In addition, this year, Congress is discussing the Federal Laboratory Technology Utilization Act, which would allow labs and industry to acquire patents, and share profits based on them.

Yet another instance of Federal labs seeking to do more with industry lies in the broader uses of state-of-the-art machines that are placed in national labs. These are called user facilities, but customarily the primary users were the labs themselves and universities with which they had connections. Now, labs are reaching out and trying to get the attention, interest, and participation of industry in making the most of these user faciliites. An example is Brookhaven National Laboratory's synchrotron light source, where the lab is brokering three-party relationships among itself, universities, and industry. Hopefully, such a relationship at an early point in research will help speed the process by which basic research can be translated into commercially viable products. Also, labs are obliged under the Stevenson-Wydler Act of 1980 to spend 0.5 percent of their funding to transfer developed technology to alternate users, including industry.

Other examples might be found. The point is that there are interesting examples—indeed exemplary cases of—of innovative lab activities that lie in the economic development sphere. These ad hoc activities are taking place because there are national needs and a desire on the part of the labs to find ways to meet them.

These Federal laboratory responses are nevertheless fragmented and ad hoc because there really is no national mission in economic development. There is, of course, no end of debate about industrial policy. Unfortunately, the country has not yet resolved how to translate industrial policy ideas into a national program, and how to relate science and technology, including the Federal labs, to such a derivative mission. Hence, there is activity—much of it significant—but there is little coordination among the labs with respect to these activities. The whole may be less than the sum of the parts.

Conclusions. What lessons can be derived from this review of recent history? One, the story of Federal labs and Federal policy is one of continuity, change, and conflict. The greatest continuity is seen where there is relative consensus as to national need and mission; for example, defense, health research, standards, and measures. Where larger policy consensus is lacking, for example, civilian energy, there is change and conflict.

Two, the major civilian labs in space and energy have experienced an ebb and flow in national priority with respect to their

missions. They have also experienced shifts in political sentiment as to their roles. What should Government do versus what should the private sector do? Today, this is particularly true of the energy labs.

Three, institutions can shrink as their missions decline. But, history shows that missions can go down and then come up again in importance. Space is a classic instance of this ebb-and-flow effect. Hence, there may be need for maintaining institutional strength in the Federal labs, as a buffer against future uncertainties. This can be done only by such labs becoming resilient and adaptive. Diversification as to sponsor and performing appropriate work for others are logical strategies. This has been attempted by many labs.

Four, it is in the nature of multiprogram national labs in particular to respond to national problems, rather than profit opportunities or discipline-based needs. Today, with the relative decline of energy as a mission, there is a particular desire on the part of these labs to deploy to what is perceived as the emerging national need of economic development in those areas where there is strong technological competition from abroad. In the absence of national policy which articulates an R&D strategy as to what is a sensible and legitimate way to go in this area, labs are relating to this need as best they can, ad hoc, usually in a highly individualistic manner.

Five, while the above leads to creative entrepreneurship at the laboratory level, it may also be inefficient, unsuccessful, and even inappropriate. Certainly, it would be better for them to diversify if they did so in the context of a national policy, in which a mission was clear and their role spelled out.

Six, nothing is more obvious than that the laboratories are here to stay. There needs to be more conscious thought given to their care and feeding, for purposes of maintaining vitality and excellence. A clear understanding of how national policy or lack thereof impacts on labs would be in everyone's interest. It may be useful for America to learn lessons about the role of Federal laboratories from other countries that have used them differently than the United States has. Since Japan is a chief competitor in high technology economic development, it is useful to note what it does in terms of national laboratories. In Japan, science and technology policy has been coordinated with industrial policy. Thus, according to a recent study by the Organization for Economic Cooperation and Development, OECD, in Japan:

> R&D programs have been designed to create a technological capability in the key sectors identified by industrial policy as important for the future, and national laboratories, about 20 in number, have been the focal point for catalyzing efforts of universities and firms and disseminating research results (Jean-Eric Aubert, "Innovation Policies—A Three-Way Contrast," *OECD Observer,* Nov. 1984, p. 9).

Obviously, adaptations of foreign institutional approach to the U.S. context would be necessary, assuming that this country deemed the Japanese approach desirable. This would require conscious strategy rather than a piecemeal backing into policy, which now seems to be the case.

Seven, all this comes down, ultimately, to recognizing that the United States has a resource and that this resource—its Federal laboratories—needs to be used effectively. The labs are means,

however, not ends in themselves. Hence, effective use of the Federal labs depends first on having effective national science and technology policies that move with the times. These hearings will hopefully serve to help develop such policies. It is commendable that this congressional committee recognizes the critical interdependence of Federal laboratories and Federal policies.

[The prepared statement of Dr. Lambright follows:]

FEDERAL LABORATORIES AND FEDERAL POLICIES: EVOLUTION AND CURRENT TRENDS

W. Henry Lambright, Professor
The Maxwell School
Syracuse University

and

Director
Science and Technology Policy Center
Syracuse Research Corporation
Syracuse, New York

Testimony before U.S. House Committee on Science and Technology
Science Policy Task Force Hearings
on
Science in the Mission Agencies and Federal Laboratories

October 2, 1985

At the core of federal science and technology policy are the federal laboratories. These often ignored and frequently maligned institutions are one of a number of performers (universities and industry are the primary others), but they are unique in being of the government. This is true whether they are civil service labs or government-owned, contractor-operated. They are extensions of government policy. As such, they provide a technical base of knowledge to the agencies that give them support. They help advise in setting federal science and technology policies through their agency sponsors; and then they play a large role in implementing those policies as performers of research and development (R&D) and as managers of the work of universities and industry. These are institutions in the middle, and as one would expect of institutions in such a position, they are often subject to various cross-pressures.

Who governs the federal laboratories? Who influences the direction and pace of their R&D programs? What are the current pressures on and within the laboratories? What are the trends? Where have they been? Where are they headed? In addressing these questions, we will be focusing on the policy issues.

Federal laboratories and federal policies are supposed to go hand-in-hand. But sometimes they do not. Federal labs may be part of or extensions of government, their dominant sponsor. But they also are semi-autonomous, frequently as a matter of deliberate design by their creators. They have minds--or policies--of their

own. Sometimes such policies are different from federal policy. This may be good or it may be bad, but it is an inevitable consequence of the size, pluralism, and complexity of the American science and technology enterprise.

The Nature of Federal Laboratories

The federal laboratory universe is both huge and diverse. There are more than 700 laboratories in the United States. As noted, these vary greatly in form. Over the years there have been numerous consolidations and even some closings. There were once over 1000 federal laboratories.

A great deal of federal R&D funds flow to these organizations--approximately one-third (Progress Report on Implementing the Recommendations of the White House Science Council's Federal Laboratory Review Panel, Vol. 1, Summary Report, July 1984). The 1985 Department of Energy (DOE) funding to the 12 multiprogram labs alone was almost $4 billion.

These are usually large institutions, employing sometimes many thousands of people per lab. Oak Ridge National Laboratory (ORNL) alone has almost 5000 employees, while Lawrence Livermore employs over 7000. Collectively, the federal laboratories employ nearly half a million scientists and engineers.

Not only are they large in terms of employees, but the federal laboratories house some of the most expensive and sophisticated scientific equipment in the world: high-voltage electron microscopes, synchrotrons, complex computer equipment, satellite microprocessors, telescopes, atomic resolution microscopes, proton accelerators, and other frontier tools. Often, scientific experiments can only be performed when a particular combination of equipment--sometimes large and expensive--is available in one location. Many of the federal labs contain these unique and necessary combinations of equipment. For example, at ORNL, the close proximity of a 30-meter, small-angle neutron scattering instrument and a companion 10-meter, small-angle X-ray scattering instrument to compare results is extremely important in many areas of polymer chemistry.

As to quality, it is natural that this large number includes everything from the outstanding to the mediocre. Among the stronger federal labs are those that are called "national labs." Exactly what makes a national lab different from a federal laboratory has never been spelled out in any precise way. In the beginning of the 20th century, the National Bureau of Standards (NBS) was established and perhaps pioneered the model.

That is, while located under a specific agency, this laboratory had a mission that went beyond that agency and reached to other agencies and the nation-at-large. Today, we have many laboratories that have "national" in their titles: e.g., Argonne National Laboratory; Los Alamos National Laboratory (LANL); and National Institutes of

Health (NIH). But there are organizations that behave as "national" institutions which do not have this designation: e.g., Jet Propulsion Laboratory (JPL).

The notion of the "national laboratory" is not just a matter of verbal ornamentation. It reflects a perception, held both inside and outside the lab, that these institutions are national resources, rather than strictly agency resources. As Congress knows, what people think can be as important as what is, where federal policy-making is concerned. It can affect behavior and the relative independence of national laboratories as compared with other federal laboratories. The relation of federal laboratories to government is somewhat open-ended. Government means more than the dominant agency to which labs report. Government means other agencies, Congress, and the President. This is because those other institutions see these institutions as separable from agency sponsors--too important to be just the concerns of those agencies.

It is recognized that federal laboratories ("national" and otherwise) are crucial to the implementation of U.S. science and technology policies. The fact that these hearings are taking place, in which the federal labs are a focus of attention, underlines the point. These hearings are the latest of a sequence of studies of the federal laboratories including one for the White House under David Packard. What is not so well recognized is the fact that these institutions have missions and roles that are self-generated as well as provided to them. Sometimes, the policy signals they get from government--agency, Congress, President--differ or are slow to

develop. Inevitably, there are differences in ends and means among the various players in federal laboratory policy. Hence, continuity, change, and conflict take place at different times in the relations between the lab and its policy environment.

Evolution of Federal Laboratories and Federal Policies

These issues can be placed in better relief by outlining the evolution of federal laboratories and federal policy. In doing so, we will emphasize change and conflict. Amidst change and conflict, there has been much continuity, as in the case of NBS, NIH, and most Defense Department labs. There has been more turbulence in connection with space and energy labs. The labs associated with this area of policy--especially the civilian energy labs--have been the ones that have been at the heart of the recent controversy.

It is useful to discuss the evolution of federal labs and federal policy in terms of six phases: (1) the World War II "revolution" in federal science and technology policy, 1940-1945; (2) the atomic energy era, 1945-1957; (3) the space era, 1957-1969; (4) the era of uncertainty 1969-1973; (5) the energy era 1973-1981; and (6) the second era of uncertainty, 1981-present. These phases bring out differences in emphasis in federal civil science and technology policy. These represent the major policy shifts for the labs.

World War II and the Revolution in Federal Science and Technology Policy, 1940-1945

Before World War II, most federal science and technology was carried out in federal laboratories or in university laboratories related to the Department of Agriculture. Agriculture was in fact the dominant civil science agency. But funding was small--$50 million--and few science and technology issues gained the attention of federal policymakers.

World War II changed all this. The U.S. began spending billions, and doing so in institutions only loosely connected with government. America created the "contract" state, wedding industry and universities to federal R&D, and making science and technology a major subject on the agenda of federal decision makers.

The Atomic Energy Era, 1945-1957

What was created by the war were a number of new laboratories that sought to link science with technology. These were more than research institutions; they were what some have called technology development organizations. Their objective was to create new capabilities that for one reason or another could not be created by universities and industry. These capabilities required special equipment, organized teams of scientists and engineers from a range of disciplines, and often entailed a measure of hazard, as well as national security considerations.

Atomic energy obviously was the premier new capability to be developed. Further work had to be accomplished with bombs: first the atom bomb, then the hydrogen bomb. In addition, work went into reactors to power first ships and then civilian electric plants. Federal policy, such as Eisenhower's atoms for peace program in 1953 and the rewriting of the atomic energy act in 1954, encouraged the laboratories created by the war in this civilian direction. The labs were called national labs and in fact had their origins before the agency under which they were placed--Atomic Energy Commission (AEC).

By the late 1950s, this mission of civilian nuclear power had become a large enterprise for various AEC labs, one they wished to continue indefinitely. As various light water reactor designs moved from R&D to commercialization under industry in the 1960s, the labs looked to the next generation of technology. This was defined as the liquid metal fast breeder reactor (LMFBR). For the atomic energy labs, there was a measure of continuity. They had become accustomed to a certain style of work--"big science," organized around big programs and large-scale, long-term missions. LMFBR, however, could not absorb all the national lab talents in the 1960s that had been built up in the 1950s. So, in some AEC labs, there was a beginning at diversification. However, in the 1960s, the more significant changes in federal policy affecting federal labs were not in atomic energy at all. They were in space.

The Space Era, 1957-1969

Sputnik ushered in the space era for federal policy and federal labs. Again, as with atomic energy, the labs preceded the agency, National Aeronautical Space Administration (NASA), which was created in 1958. The institutional core of NASA was a group of aeronautical laboratories inherited from the National Advisory Committee for Aeronautics (NACA). Also placed under NASA's jurisdiction was the rocket laboratory, headed by Wernher von Braun, formerly under the U.S. Army at Huntsville, Alabama. Also moved under NASA was JPL. Finally, NASA created some additional labs (e.g., Manned Spacecraft Center in Texas and Electronics Research Center in Massachusetts).

These vast changes reflected the new space mission. This mission also meant a change in style. The old NACA aeronautical labs largely did work in-house. The NASA style was to do some work in-house, but also to use labs to help manage huge contracts with industry.

While America was going to the moon, the big NASA labs did well. This was because their missions matched what their agency wanted to do and what the nation--through Congress and the President--wanted. As with the nuclear labs, space involved a very large-scale technology mission that matched the scale of the labs themselves. These were "big science" organizations. They used large-scale equipment

and they mobilized large numbers of scientists and engineers around big technical problems associated with these missions. There was a synergism.

But by 1969, the juxtaposition of federal policy, agency, and labs was coming uncoupled. The country was losing interest in space, and nuclear energy was becoming a target of environmentalist critics. Science and especially technology were in trouble, seen as problems rather than solutions.

An Era of Uncertainty, 1969-1973

There was continuity in space and energy in this next era, 1969-73. But, there were change and conflict also. For both the space and atomic energy labs, there were substantial cutbacks and doubts about the future. The mainline civilian missions--nuclear reactors and manned space--were in trouble.

There was much talk about redeployment and "work-for-others." The Electronics Research Center was in fact killed as a NASA lab, only to be revived and restaffed as a Department of Transportation lab. There was talk and some effort to use aerospace specialists in other domestic areas--technology transfer to state and local government was particularly in vogue at this time. The Nixon Administration spoke of a New Technology Opportunities Program.

But, these domestic missions simply were not well enough funded to absorb the large-scale enterprises. Having created huge, mission-oriented science and technology installations, there was a need to find huge missions on which they could work. For the space labs, the uncertainty, lay-offs, and underemployment came to an end in 1972, with the national decision to build a Shuttle. For the atomic energy labs, it came to an end with the energy crisis, beginning in 1973. For NASA, there was continuity in mission. For the nuclear labs, however, there was change.

The Energy Era, 1973-1981

While manned space began coming back in the 1970s, it was energy that was the dominant civil science and technology mission. Between FY 1974 and FY 1977, space expenditures remained relatively constant at about $2.7 billion, while energy funding soared from $1.1 billion to $2.8 billion. This represented a greater than 100 percent increase for energy.

As a consequence, many of the NASA labs got into the energy business--a wind-power, for example. This was indicative of the change in energy R&D--from nuclear to energy-in-general. AEC gave way to the Energy Research and Development Administration (ERDA) in 1975; and ERDA in turn was subsumed by DOE in 1977. The labs continued as these reorganizations in Washington took place. However, they broadened and grew, and diversified into solar, wind, fossil fuels, fusion, and various other areas. Even the weapons labs, such as LANL, became quite a significant force in certain alternative energy

sources, notably solar energy. And, in 1975, a new laboratory which focused on solar, Solar Energy Research Institute, was created. In some ways this stood as a symbol of the nation's long-term investment in an alternative to nuclear and fossil fuel resources.

During the mid and late 1970s, therefore, energy R&D loomed large, even as nuclear R&D (and particularly the LMFBR program) diminished in priority. Labs found plenty to do on energy. After President Carter proclaimed a national synthetic fuels goal in 1979, the future seemed relatively certain and secure for the energy labs. So persuaded was everyone that energy-in-general was going to be the "big science" mission for a long time to come that NASA began actively promoting multi-billion dollar energy systems from space.

A Second Period of Uncertainty, 1981-Present

In 1981, the Reagan Administration took office. This coincided with a sharp diminution of the energy threat from OPEC. The Reagan Administration decided that energy was no longer a top priority in federal science and technology. Indeed, the Administration sought to dismantle DOE, only to be stopped by Congress. Significantly, however, there was no serious thought given to abandoning the national laboratories under DOE. These would be preserved in part because some of them--e.g., LANL, Lawrence Livermore, and Sandia--were primarily weapons labs. Also, all the DOE labs had a great deal of political support and recognized merit independent of DOE. There could be sharp controversy about DOE, in part because of its regulatory responsibilities. But there is relative consensus about

the importance of the labs. The big question for a while was where to put them, and one candidate was the Department of Commerce. Nevertheless, with the lessening of funding for energy, the civilian energy labs needed to ask about missions and roles again.

Missions have to do with energy, space, defense, or some other national problem. Role pertains to whether the labs have a place in a given field at all--or should it be the role of the university or industry to be engaged in a particular mission. The Reagan Administration, more than any other in the history of labs, raised the question of role, and did so in a way as to narrow considerably what they had been doing. Specifically, it said that the role of the labs was to perform research that was relatively basic and long-term, of a high risk character, and work that could not or would not be done by the private sector. This meant that the role of the labs in demonstrations and commercialization was curtailed dramatically, while that in basic research augmented. What the labs were supposed to do about technology development was unclear.

So, the civilian energy labs had a problem of diminished mission and narrowed role in the 1980s. Also, longstanding conflicts with industry and universities reemerged, given a smaller energy R&D pie to divide.

Ironically, the manned space labs of NASA were doing all right in the 1980s as the Reagan Administration gave a priority to space R&D it withdrew from energy. The Shuttle was continued and the Manned Space Station decision made. Hence, the space labs had relative stability in their environment in terms of mission and role.

The most significant development was with the Department of Defense (DOD). Its R&D funding was growing. This meant that both the NASA and DOE labs could try to obtain support from this source, and some of them did so to avoid lay-offs. While manned space missions were doing relatively well, some of the unmanned science satellite programs were not. JPL, which saw some of its programs in this field diminish, looked toward DOD for bolstering.

It was one matter for the NASA labs to supplement their work through DOD, whose own space programs were growing. It was more difficult for the civilian energy laboratories to go in this direction. As a result, a number of the civilian energy labs are shrinking.

What has been happening has been a searching for new missions by the civilian energy labs. This search has been wide-ranging, well beyond DOD. For example, ORNL has moved vigorously into disaster work for the Federal Emergency Management Agency and into international energy research for the Agency for International Development. But perhaps the most important, intriguing, and problematic new mission emphasis is economic development.

There is increasing recognition that international competition among high technology nations is creating serious new problems for the U.S. The nature of national labs is to relate to national problems. There have been some seminal relationships established. For example:

* The White House Office of Science and Technology Policy was the principal advocate behind a new national laboratory-steel industry research program that is currently evolving. This is a partnership "in which the steel industry, two national laboratories of DOE, and the NBS are working together to develop 'leap frog' technology to help the steel industry achieve increases in productivity, meet foreign competition, and prepare for the 21st century." Science Adviser Keyworth has explained: "One practical result is to marry the technical expertise of the labs with the needs of the steel industry. The national labs will not do the steel companies' jobs for them; this program provides access for a threatened and important domestic industry to existing taxpayer-supported technical resources" (Alan Schriesheim, "Federal R&D Policy, Science, Vol. 226, Nov. 16, 1984; George Keyworth, "Science and Technology Policy: The Next Four Years," Technology Review, Feb./Mar. 1984, Vol. 88, No. 2).

* There is an enormous interest in economic development coming from various states and some local governments. As labs in the early 1970s sought to be relevant to problems of cities and other public service areas, so in the mid-1980s they are

groping to find economic linkages with industry and universities at the regional level. It is a fact that in some areas federal laboratories are the key technical resource. States see this, and are themselves seeking to facilitate relationships for economic development. One new relationship is taking place along the corridor between ORNL and Knoxville.

* A major policy development relevant to lab-industry linkages, and thus economic development, has to do with patent policies. For years, relations between labs and industry were inhibited by industry fears that government would take patent property in inventions such relationships might have produced. Now there are changes taking place. For example, in 1980, Congress passed the Bayh-Dole Act, which granted small business firms and not-for-profit organizations greater opportunities to acquire patent rights for federally funded inventions; in 1985, Congress is considering extending the same principles to large business firms. In addition, this year, Congress is discussing the Federal Laboratory Technology Utilization Act, which would allow labs and industry to acquire patents, and share profits based on them.

* Yet another instance of federal labs seeking to do more with industry lies in the broader uses of state-of-the-art machines that are placed in national labs. These are called "user facilities," but customarily the primary users were the labs themselves and universities with which they had connec-

tions. Now, labs are reaching out and trying to get the attention, interest, and participation of industry in making the most of these user facilities. An example is Brookhaven National Laboratory's synchrotron light source, where the lab is brokering three-party relationships among itself, universities, and industry. Hopefully, such a relationship at an early point in research will help speed the process by which basic research can be translated into commercially viable products. Also, labs are obliged under the Stevenson-Wydler Act of 1980 to spend .5 percent of their funding to transfer developed technology to alternate users, including industry.

Other examples might be found. The point is that there are interesting examples--indeed exemplary cases--of innovative lab activities that lie in the economic development sphere. These ad hoc activities are taking place because there are national needs and a desire on the part of the labs to find ways to meet them.

These federal laboratory responses are nevertheless fragmented and ad hoc because there really is no national mission in economic development. There is, of course, no end of debate about industrial policy. Unfortunately, the country has not yet resolved how to translate industrial policy ideas into a national program and how to relate science and technology, including the federal labs, to such a derivative mission. Hence, there is activity--much of it significant--but there is little coordination among the labs with respect to these activities. The whole may be less than the sum of the parts.

Conclusions

What lessons can be derived from this review of recent history?

1. The story of federal labs and federal policy is one of continuity, change, and conflict. The greatest continuity is seen where there is relative consensus as to national need and mission (e.g., defense, health research, standards and measures). Where larger policy consensus is lacking (e.g., civilian energy) there is change and conflict.

2. The major civilian labs in space and energy have experienced an ebb and flow in national priority with respect to their missions. They have also experienced shifts in political sentiment as to their roles: What should government do versus what should the private sector do? Today, this is particularly true of the energy labs.

3. Institutions can shrink as their missions decline. But, history shows that missions can go down and then come up again in importance. Space is a classic instance of this ebb and flow effect. Hence, there may be need for maintaining institutional strength in federal labs, as a buffer against future uncertainties. This can be done only by such labs becoming resilient and adaptive. Diversifica-

tion as to sponsor and performing appropriate "work for others" are logical strategies. This has been attempted by many labs.

4. It is in the nature of multiprogram national labs in particular to respond to national problems (rather than profit opportunities or discipline-based needs). Today, with the relative decline of energy as a mission, there is a particular desire on the part of these labs to deploy to what is perceived as the emerging national need of economic development in those areas where there is strong technological competition from abroad. In the absence of national policy which articulates an R&D strategy as to what is a sensible and legitimate way to go in this area, labs are relating to this need as best they can, ad hoc, usually in a highly individualistic manner.

5. While the above leads to creative entrepreneurship at the laboratory level, it may also be inefficient, unsuccessful, and even inappropriate. Certainly, it would be better for them to diversify if they did so in the context of a national policy, in which a mission was clear and their role spelled-out.

6. Nothing is more obvious than that the laboratories are here to stay. There needs to be more conscious thought given to their care and feeding, for purposes of maintaining vitality and excellence. A clear understanding of how

national policy (or lack thereof) impacts on labs would be in everyone's interest. It may be useful for America to learn lessons about the role of federal laboratories from other countries that have used them differently than the U.S. has. Since Japan is a chief competitor in high technology economic development, it is useful to note what it does in terms of national laboratories. In Japan, science and technology policy has been coordinated with industrial policy. Thus, according to a recent study by the Organisation for Economic Cooperation and Development (OECD), in Japan:

> R&D programs have been designed to create a technological capability in the key sectors identified by industrial policy as important for the future, and national laboratories (about 20 in number) have been the focal point for catalyzing efforts of universities and firms and disseminating research results (Jean-Eric Aubert, "Innovation Policies--A Three-Way Contrast," OECD Observer, Nov. 1984, p. 9).

Obviously, adaptations of foreign institutional approach to the U.S. context would be necessary, assuming that this country deemed the Japanese approach desirable. This would require conscious strategy rather than a piecemeal backing into policy, which now seems to be the case.

7. All this comes down, ultimately, to recognizing that the United States has a resource and that this resource--its federal laboratories--needs to be used effectively. The labs are means, however, not ends in themselves. Hence, effective use of the federal labs depends first on having effective national science and technology policies that move with the times. These hearings will hopefully serve to help develop such policies. It is commendable that this congressional committee recognizes the critical interdependence of federal laboratories and federal policies.

Mr. FUQUA. Thank you very much, Dr. Lambright.

In the closing part of your statement you were talking about national labs had to be resilient to keep up with the changing times when we have the ups and downs of what is vogue today is not tomorrow.

How do you keep good researchers interested in that, if you have someone working in energy, and the lab director comes in today and says, "I am sorry, that is not high priority today, you are going to do something else. We are taking a lot of your money away because Congress and OMB and the administration has changed policies"? What happens to that person; how do they sustain after that what they have been involved in for a long time, very devotedly, and then come back a year or two later and say today we need to get you back on the project you were working on?

Dr. LAMBRIGHT. There is a famous book that came out some years ago that talked about an organization called "Exit Voice" and it was essentially a response to decline. How do institutions and people respond to decline or problems in their environment? One is to exit, leave. A man can essentially say, "I am not an energy man, and I am going. I cannot live with the change, I am therefore going to leave this laboratory and go to another and do that."

A voice. A voice means protests. He tries to change the mind of the superior, he tries to say that energy is important and that we should try harder to say in this business.

Loyalty is one where the man goes along with the directive from his superior. Where you are loyal to your organizational superior, and you are forced to change, you sometimes do. You nevertheless must have work that is interesting to stay on the peak of your field and so the dilemma is really with those individuals who choose to stay and are moving into different areas.

If they have another mission area to move into, that keeps them excited, that is equally challenging, it is all well and good. But more often than not, it isn't easy to move into new areas, so that individuals retreat to an individual kind of research. That might be down in universities where an individual professor does his own thing and where you hope they are doing mission-oriented work.

If there is an alternate mission for that man who stays in the lab to work on, he will retreat to doing individualistic kind of projects which may be interesting to him but do not necessarily serve the country's interests, and which might be more appropriate to the university than to a national laboratory.

Therefore, what I am essentially saying is for those individuals who choose to stay, the answer to keeping resilient is having another applied mission equally interesting and important to that man.

Dr. TEICH. If I may add just a small bit to that, the problem doesn't always arise quite that directly. There may often be sciences, as you know, where research in a given area may be applicable to others. One is photovoltaics, which of course were developed in NASA laboratories. A considerable amount of work was done on them in NASA laboratories in the period when space research was

a high priority mission and one of Dr. Lambright's historical periods, and which subsequently found a great deal of applicability to energy, alternative energy research. So that a given piece of research can be applied to more than a single mission and one of the strengths I think of many of our Federal laboratories is their ability to do work that can be applicable to different missions. And I think that one of the things we need to take a better advantage of are the synergisms between different areas of research and the applications of given areas to more than one national mission.

Mr. FUQUA. What should be the criteria for reorganizing the present laboratories or creating new ones?

Dr. LAMBRIGHT. What should be the criteria?

Mr. FUQUA. For reorganizing present—going back to the Packard Commission, which was also initiated somewhat by the urging of this committee of the role and scope of national laboratories, so that with limited funds, we did not have laboratories because they are running out of projects trying to compete against others. Or for instance, there was one of the laboratories that was doing extensive work in forestry. Every land grant college in the country has a forestry school. It didn't seem really appropriate for that energy lab to be involved in forestry. How do we make sure that they do not compete against what can legitimately be done in colleges and universities and at the same time provide the resources that the Government needs? Should there be any reorganization, and what should be the criteria for them?

We have had one laboratory right now in dire straits because they ran out of work. They worked themselves out of a job and they are hurting now. They are scrambling trying to find things that they can do to keep their team going.

Dr. LAMBRIGHT. Well, I think that the answer to that question is if one looks for an answer by examining the record, history, which is the best way of trying to think about a question like that, the country has had ups and downs in missions in the past where there essentially has been underemployment of laboratories and the country has had to address the question in the past.

So what has been some of the criteria that have been employed in the past for this same issue? I remember—I am sure Al does, too—in the era of the late sixties when NASA had its peak and was beginning to go down. There was a serious question: "Do you need all of these laboratories, NASA? Do you need all of them? Should we get rid of some of these labs? Can you reorganize them and go move some of these to new missions?"

NASA made the point that certain laboratories were absolutely core to its mission and that these had to be maintained as Government institutions because not only did they do work but they also helped provide the technical expertise to the agency which it needed to govern industry and the universities. So it drew the line.

It could not draw the line at certain other institutions and I recall one laboratory, one called the Electronics Research Laboratory, which had been set up on Boston, MA, where it was argued that this was no longer as necessary to NASA as it might have been in another era. The question then was what was to be done with this surplus institution and was there another mission to which you can deploy this electronics research institution?

It happened there was another mission coming up and the mission was the Department of Transportation. It made the argument. "We, like NASA, not only had to do research, we need a technical expertise that we can depend on that is of the Government and therefore we need a laboratory that will provide that expertise." There had therefore to be a genuine redeployment of institutions there from one agency to the next. It was canceled as a NASA lab, and it was then redeployed to a Department of Transportation lab.

The criteria, however, were more complicated than simply shifting one to the other, because in effect when you moved one lab from a declining mission to a mission environment that was coming up, you had a mismatch. In effect, the laboratory employed high space technical engineers. The people needed in the Department of Transportation were different kinds of engineers. So gradually over time, the laboratory took the shape of its new parent, which was the Department of Transportation.

In effect the criteria in this instance were if there was a mission available and if there is a mission, is there enough match that you can move the lab to the next mission, and if there isn't, do you have to make changes in the lab in terms of employment. That was in effect done. If you move that to the present era, you would have to ask, if you have laboratories that are declining, is there another Government agency with a mission that can go up, and that needs a capability?

If the answer is yes, then you will retain—it is easier to change, it is easier to keep a laboratory and change it than to create a whole one from scratch. But if there isn't, then I think you have to entertain questions that you don't like to entertain. Do you cancel or terminate certain institutions? If there had not been a Department of Transportation available for the Electronics Research Laboratory, it seems to me that an appropriate policy decision might have been to have terminated it and to let some of the work go to industry and the universities at this point in history.

Mr. FUQUA. Mr. Brown.

Mr. BROWN. Gentlemen, let me ask just one question dealing with how we can better organize and manage this tremendous resource which staggers the imagination almost, particularly if one is not involved in it. Didn't one of you mention a figure of $4 billion just for the Defense Department?

Dr. LAMBRIGHT. Just for the national labs under DOE.

Mr. BROWN. And the total for all the national labs is what? Can you offer an estimate?

Dr. LAMBRIGHT. I had one-third of the Federal R&D.

Mr. BROWN. One-third would be about?

Dr. LAMBRIGHT. All the labs?

Mr. BROWN. Seventeen billion dollars or something like that. Which is a very large resource and involves what, 50,000, 100,000 people or something of that sort?

The question emerges of how do you manage this system in such a way as to get the maximum national benefit, particularly considering this phenomena of ebb and flow and change in mission and so on, which is now handled pretty much on ad hoc basis. I remember when JPL went through the trauma of a reduced space mission and they had to look for other missions, they went to DOD, a rea-

sonable place to go. But I think they did this more or less on their own, looking for what were the most compatible programs to utilize the resources that they had there, and they are to be commended for doing that, but it produced some transitional change in personnel at the same time.

In this committee, we have kicked around the idea from time to time of establishing an organization to deal with the problems of technology management and development, something paralleling the National Science Foundation, for basic research, but dealing more with the problems of technology base and economic development, and I am wondering if that kind of concept could be refined to include establishing a structure of that sort with a major role in terms of just keeping on top of the national laboratory resources and helping it to define missions, realign missions, to identify priorities, and to refocus it in a new area when it was necessary to do so.

We have, for example, a growing need for materials research and we are funding materials laboratory development now. I am not sure we are doing that in a coordinated way. As a matter of fact, both the executive branch and Congress probably could use some better tools than we have for making that kind of a determination.

Dr. LAMBRIGHT. I think what you are saying is correct. What I have observed is that there is a great deal going on at the laboratory level reaching out for, say, a mission like economic development. It is very ad hoc and entrepreneural. Much of it is taking place in connection with State government, which is I think a very good development. The national policy has been relatively permissive with respect to what the labs do.

Mr. BROWN. Let me give you one other example—the steel initiative—which apparently originated in the executive office and which is a very commendable initiative. It was responsive to a lot of demands here in Congress to do something for the steel industry. They have conceived a plan which I think is reasonable, to involve several of the national labs in partnership with the steel industry and other institutions, I presume, to do something about making some breakthrough developments in steel.

Would it not have been better if we had had some sort of an institutional structure which could have identified a pressing problem like this, and made the recommendations to the White House or to Congress, that we ought to do something of this sort, and to deal with other problems? There are other things than steel that we are concerned about.

Dr. LAMBRIGHT. My answer is absolutely yes, and I think that this comes up over and over again and 8 times out of 10 opportunities are missed because there is no structure to deal with this.

Mr. BROWN. There is a little incoherence in philosophy also, which makes it difficult to deal with some of these problems.

Dr. LAMBRIGHT. It basically is a market approach we are using with respect to the labs in the sense of their initiative. The labs go where they can. If a lab sees layoffs coming, it then seeks out support from the Department of Defense or wherever it can get support to avoid layoffs.

Mr. BROWN. But a lab couldn't come up with something like a steel initiative because that involves a policy decision that goes far beyond the laboratory itself.

Dr. LAMBRIGHT. What the lab can do easily is move into areas that are an extension of what it already does, more or less. What the lab can't do is make a radical jump into a totally new relationship involving real change.

Dr. TEICH. May I speak to that?

Mr. BROWN. Yes.

Dr. TEICH. I think you have put your finger on it, phrasing this question on an important aspect of it, and that is the notion that we have a national system of laboratories and very seldom do we really think in terms of these laboratories as a system, which I think more as with terms of the laboratories of each agency—of the DOE laboratories, or EPA, or Department of Defense, and so on. That is characteristic, of course, of the way the Government is organized, and it is important at one level to maintain that kind of structure, because the laboratories do have important missions which need to be served and that is, in most cases, their essential and first priority.

I think by conceptualizing, viewing these institutions as a system, and establishing some kind of a structure which can make use of them in a coordinated way, without detracting from their ongoing missions, but on top of it essentially, I think we could accomplish a great deal in the steel industry initiative, or similarly, I guess that would serve such national needs that are being served, otherwise it is a very good example.

We need to set up a structure that could take advantage of the commonalities of laboratories, that can view them overall as a resource and within the pluralism, without trying to bring them all under a single roof, can employ the pluralism of resources in a coordinated way.

Mr. BROWN. Of course, we have to be careful at the same time that we don't create a rigid, centralized system of control that threatens the relationship between the mission agency and the individual labs, and in the same way, that we have to be concerned that the NSF doesn't exercise some autocratic control over the way basic research is conducted around the country.

Dr. LAMBRIGHT. What we are saying is that you need a supplement to what exists that is in everyone's interests in effect. We have to assume there will be an ebb and flow and history shows us this is the case. Therefore, when you have the shifts in a situation, when national policies change and you have these institutions and you have a mismatch, if you do not act to make adjustments, what will happen will be inefficiencies, layoffs, the loss of talented people, and the country will not get its best from this particular resource.

Mr. BROWN. I remember the frustration that the chairman of the Appropriations Committee expressed several years ago about these multitudinal national labs. There were 800 at that time. Nobody could tell him how many there were, what they were doing or anything else. He did apparently authorize a special Appropriations Committee study to ferret out all of what was going on in the Federal laboratory system, in order to be able to do a more intelligent

job of making policy at the level of the Appropriations Committee. I am not sure he succeeded, but it reflected the lack of any central source of even information about all of the activities of the Federal laboratories at that time.

Dr. LAMBRIGHT. It would help individual laboratories just simply to know what other laboratories are doing in terms of these economic development initiatives with the States.

Mr. BROWN. Mr. Ritter.

Mr. RITTER. Thank you, Professor Brown. I think you have made some very salient points.

I would like to thank our two witnesses. I think that they have given us the kind of background to deal with the problem, which is right here, it is right now. There is I believe something we can do about it. It is not one of these problems that are so long range, so far out of the jurisdiction we can't come up with potential policy solutions.

You know the Democrats to some extent have defined this realm of industrial policy. The Republicans have talked about industrial competitiveness. To some extent, policy from the Democratic perspective has to have some hierarchy of decision power and to some extent, the Republican response on industrial competitiveness has been to create a complement for innovation and invention. But I must say, that in this arena, there may well be some shared common ground, shared ways of going about it. There is still a real opportunity given this area of uncertainty, as you mentioned.

Then the question becomes, given the complexity of all of these different institutions—there are far reaching geographic, political constituencies—the question then becomes under what Federal policy aegis does this reorientation take place? And if orientation is defined by a desire to integrate a little industrial policy with creating the climate for industrial competitiveness, therefore, the necessity for involving a very high degree of private sector input, industry input, how do you foresee a scenario like that taking place? What is the relevant Government agency? Is it OSTP; is it OMB; is it some mega-mission agency? Somewhere, somehow, somebody has to have the opportunities for this if it is going to happen.

Dr. LAMBRIGHT. Well, I think that because of the fact that labs are under—the organization of the Government is such that labs are essentially underneath agencies, and agencies are very jealous of their labs. Even if a laboratory may be in the state of decline, there is the fear that another agency may grab some of its best people that are in that particular lab to work on its projects.

So it seems to me if you are talking about a system where you have an initiative and a system that can relate these laboratories to new missions, and if industrial policy or industrial competitiveness is the new mission, how could you relate this resource to the new mission, you are talking about something where it seems to me there is a top management need or strategic management need.

I would say it has to come from the White House. It has to come from OSTP and OMB. There is no other agency that exists that really can handle this particular problem that you are talking about right now. If you want to create a new agency, a brand new organization in the system, with a great deal of power to effect the policies of other agencies, that would be possible, but at the

moment, such a super-agency doesn't really exist, so therefore, you would have to do it through the OMB and through the OSTP and there is no reason why committees couldn't be constructed to advise the OSTP, which would include industrial representatives.

Mr. RITTER. How defined is the mission of the individual laboratory by rule, regulation, or legislation in terms of enabling agreements, how rigid are they?

Dr. TEICH. I think obviously that is a question you will have plenty of witnesses in the upcoming days that will have better answers than either of us, but it seems to me it varies considerably among the agencies. Some of the laboratories, as far as I know, are not defined at all in legislation and exist simply as a matter of having been created by the agencies and have a legal existence that isn't characterized by any very rigid sets of rules that exist at the laboratories, at the agencies' discretion.

Mr. RITTER. The agencies have a fairly rigid set——

Dr. TEICH. Agencies have of course their missions and I think there has been an effort in recent months to define more carefully the missions, particularly of the larger laboratories, as a management tool, in connection with the aftermath of the Packard report, to tell more specifically what each of the laboratories is supposed to do and have some measure of evaluating whether it is accomplishing its goal.

Mr. RITTER. OSTP, if I may interject, OSTP does not have the overriding clout to get some of these changes made. We saw what happened with the steel initiative. I am not criticizing it, there was natural competition between the agencies involved and the OSTP. If you wanted to do this in the way that George Brown was talking about, you would really need some kind of enabling legislation, rule or regulation, to give OSTP some of this authority.

Mr. BROWN. Would you yield?

Of course, the OSTP has been a strong proponent of some kind of structure, a departmental structure, for science and technology within which this could reasonably fit. Although there is no assurances that that will be recommended by the——

Mr. RITTER. It is not on the front burner.

Mr. BROWN. No.

Mr. RITTER. If the central focus—I think the Democrats and Republicans are agreeing on this—if the central focus is industrial competitiveness, as some feel—there is an area of uncertainty—the next energy crisis, the next space race—then you know then you need the private sector input in a way which we don't have today.

I guess, Dr. Lambright, at the end of your testimony you talked about how the Japanese organize and we may need to—we are not Japanese but we need to take a page or two from their book—there is no doubt that their agencies in the realm of industrial competitiveness are laced with private sector interagencies at every single level. In fact, you never know where the private sector ends and the Government begins in the mini-industrial lab activity. So how would we go about doing that?

Dr. TEICH. I think we have got to be innovative. I guess I would disagree in part with my colleague with respect to the role of OSTP, which I feel ought to be in this picture to the extent that a central presidential level agency needs to show its support. What-

ever agency takes over this function needs to have an indication of clout at that level, but I don't think I would give essentially a staff office in the White House operating responsibility for a function of this size and nature. I would simply try to see that the agency, whatever agency it might be, would have clout, would have an indication of support from OSTP and would operate independently.

Mr. RITTER. Do you favor the idea of a Department of Science and Technology?

Dr. TEICH. I am not an enthusiast of the department idea. I think that some of the perhaps less ambitious schemes under the National Technological Foundation proposals and similar ones have some merit that ought to be explored, short of setting——

Mr. RITTER. There is some dichotomy between the basic and applied research and the development of technology and the commercialization and there may well not be—as a matter of fact, if you use the Japanese labs as a model, you will find an incredible spectrum of continuum from the most basic research activity, but its direction and all basic research at some point is chosen for a particular direction some way. You wouldn't want to make that dichotomy, would you?

Dr. TEICH. No; I don't want to separate them, certainly not, but I don't think that under the present structure we are giving enough emphasis to the applied research side of things, and I don't see that the creation of an institution that would—or modification of existing institutions in a way as to provide for better assignment of new missions of this type to be the laboratories would necessarily separate. In fact, I think it could be viewed quite significantly as supplementing existing basic research.

I don't necessarily think, by the way, that the Japanese model, given the differences in their whole financial structure, and the differences between their society at large and ours, really is necessarily the best model for us.

Mr. RITTER. I understand that, but I am just saying there are things that we can learn from the model as we go from our period of uncertainty into our next historical use.

Mr. BROWN. Mr. Ritter, I don't want to interrupt this very important line of thinking; it ought to be pursued further, but in deference to our other witnesses, I wonder if we could just move on a little bit faster. If you have any additional questions, go ahead.

Mr. RITTER. Well, just for the record, I would like to have your comments on how, if we did go in this direction, how would we integrate the very strong private sector involvement?

Dr. TEICH. I would be pleased to submit a statement.

Mr. RITTER. I am sorry, Mr. Brown.

Mr. BROWN. I was at a meeting of the SRT subcommittee yesterday where we didn't finish with the first two witnesses until noon. I thought it was an injustice to the other witnesses.

Mr. Lewis, do you have any questions?

Mr. LEWIS. How do the labs and agencies interface with the international scientific communities? If you have covered this in your text, I apologize for not being here to hear it.

Dr. TEICH. I have not covered it in mine either, and it is an important question. It goes on at various levels, of course. In one sense, the interaction of international scientific communities goes

on as a natural part of the activities of individual scientists and scientific groups, and this is particularly strong in areas of basic research. And some of our national laboratories that perform high energy physics research, for example, which is one of the most internationalized areas of research, one finds resident scientists from other nations at the National Accelerator Lab. People are essentially permanently stationed at each other's laboratories to maintain liaison and it is a very effective form of international communication.

I think that the closer one moves into areas of mission, either economic application or national security application, the more difficult these kinds of international contacts become, and the more they tend to be carried out through more formalized structures of higher levels in the agencies.

Mr. LEWIS. Thank you.

Dr. LAMBRIGHT. I really don't have anything to add to that. That is essentially as I see the interaction. They are mainly through their individual scientists and the more basic, the easier it is for them to have interaction.

Mr. LEWIS. Thank you.

Thank you, Mr. Chairman.

Mr. BROWN. Mr. McKay.

Mr. MCKAY. No questions.

Mr. BROWN. Thank you very much, gentlemen. We appreciate your help.

CABLE ADDRESS: ADVANCESCI

27 November 1985

The Honorable Don Fuqua
Chairman
Science Policy Task Force
Committee on Science and Technology
U.S. House of Representatives
Washington, D.C. 20515

Dear Mr. Fuqua:

Thank you for your letter of 11 October and the kind words about my testimony before the Science Policy Task Force.

I was pleased to have an opportunity to contribute to this important work. As you requested, I have prepared responses to the several questions that accompanied your letter. These reponses are enclosed.

I regret that I was unable to meet the deadline noted in your letter, as I explained to Dr. Watson on the telephone. I hope that this will not inconvenience you or delay the work of the Task Force.

Please do not hesitate to call upon me if I can be of any further assistance.

Sincerely,

Albert H. Teich
Head, Office of Public
Sector Programs

COMMITTEE ON SCIENCE
AND TECHNOLOGY

Questions for the Record

Dr. Teich

1. You say on page 12 that "the reductions in applied research programs may be having impacts on institutions that are affecting their ability to conduct basic research". Could you please explain this statement, and give us some specific examples of how the current administration's reduction of applied research funding is affecting the application of basic research or the conduct of basic research?

2. You point out, on pages 14 and 15 of your prepared testimony, that the Office of Management and Budget and the Office of Science and Technology Policy are the two entities most capable of taking an overview of the basic research program. How can their role in this important function be improved? Or should it be improved?

3. What difference would it make to the performers of research if instead of mission agencies funding the majority of R&D, the science agencies funded the majority; that is, if the National Science Science Foundation were the major funder rather than the "balance wheel"?

4. What are the strengths and weaknesses of having a stronger role for the Department of Defense in the support of basic research relative to the other mission agencies? Is there an optimal balance between civilian and military support for scientific research?

5. Department of Defense and military-related DOE research and development were greater than 50% of all federal R&D in all the years since 1960 except 1978 and 1979. Since FY 1981, federal support for civilian research has decreased 17% in constant dollars, while federal support for defense research has increased 91%. What is the significance of this recent trend?

RESPONSES TO QUESTIONS FOR THE RECORD

Albert H. Teich

1. Reductions in applied research programs may be affecting the ability of institutions to conduct basic research in two ways. First, there is the matter of economies to scale. Basic research efforts and applied research efforts are not neatly segregated within institutions such as universities, nonprofits, or federal laboratories. Often they are conducted within the same laboratories, using the same instruments and support staff, by scientists working side by side. In fact, a single researcher may spend some of his or her time working on projects that officials of the sponsoring agency may classify as applied research and some on projects classified as basic research. Under such circumstances reductions in applied research efforts — if they are not offset by increases in basic research funding — can diminish economies of scale (e.g., spreading the cost of instrument acquisition and maintenance among several projects) and raise the cost of the basic research efforts.

   A second point is that the ties between basic research and application are growing increasingly strong — particularly in such fields as molecular genetics and microelectronics. Thus the issue of what is basic research and what is applied research may be more and more difficult to resolve (and less important in a policy sense). If one cannot really distinguish between basic and applied research, it seems unlikely that one can make reductions in one area without affecting the other.

2. The Office of Management and Budget (OMB) and the Office of Science and Technology Policy (OSTP) are the agencies best situated to take an overview of the federal basic research program. There are a number of ways in which this role can and should be improved. On the OMB side, the most direct way in which the agency takes an overview is in the preparation of "Special Analysis K" of each year's proposed budget. This is a very useful exercise, and its importance as a science policy tool needs to be communicated to OMB's leadership to assure that it continues to be carried out and that sufficient resources are devoted to it. As it stands, however, the analysis is mainly an after-the-fact reporting exercise. Its utility could be substantially enhanced by administrative reforms in OMB giving the unit responsible for the preparation of the Special Analysis some influence over the actual funding levels for basic research in agencies outside its present domain (espcially NIH and DOD).

   On the OSTP side, although the Science Adviser's public statements and policy initiatives give evidence of his deep concern for the health of the nation's basic research efforts, it appears that the office as a whole is too enmeshed in day-to-day problems and staff

work on such major initiatives as SDI to give sufficient attention to the overall basic research budget and to such issues as balance and priorities among disciplines. In view of the fact that OSTP is a White House staff office, it is not easy to see how the Congress might influence the manner in which in which the office's leadership chooses to allocate its efforts.

3. While I would certainly favor a significant increase in the National Science Foundation's budget for basic research, I do not think it would be in the best interest of either the performers of research or the nation for NSF to take over from the mission agencies as the funder of the majority of basic research. One reason, as noted above, is the growing connection between basic research and applications. As these ties grow stronger, the role of mission agency research becomes more important, because mission agency sponsorship can facilitate technology transfer. In addition, the feedback that potential users in mission agencies give researchers may be an important stimulant to the research. Finally, the much-cited pluralism of the current system of support gives research institutions stability based on political and administrative diversity, and multiple points of access to funding sources that a single agency cannot provide.

4. I am not aware of any analytical means of describing an optimal balance between civilian and military support of basic scientific research -- although it seems apparent that neither extreme (i.e., 100 percent military or 100 percent civilian support) would be very good. Between these extremes, the balance is a matter of the relative priority that the nation places on military and civilian matters (which varies with the international and domestic political situation) and the nature of the support systems employed by the various agencies. Some military agencies -- particularly the Office of Naval Research in the early postwar period -- have had a positive reputation in the scientific community for providing a very benign environment for support of basic research. More recently, DOD policy initiatives based on concerns about the flow of scientific information to hostile nations have rasied serious questions about DOD support of basic research. These questions have no clear-cut answers at this point, but the issue of military support of basic research merits careful attention by the Task Force.

5. In order to assess the significance of the recent trends in funding for defense and nondefense R&D one needs to disaggregate the figures within these categories. On the defense side, most of the enormous increase in R&D funding has been on the "D" side of R&D (actually in development, test and evaluation). The growth in defense research has actually been rather modest in comparison. On the nondefense side, large reductions in applied research and development in such areas as energy and environmental research, and the transition of the space shuttle out of R&D and into an operational program, have been partially offset by increases in basic research in NSF, NIH, DOE, and NASA. The result is a rather mixed bag for the nation's R&D efforts. On the whole, this situation is a result of the administration's priorities and interests, rather than specific decisions made on the basis of factors internal to R&D. In my personal view, the administration's extravagance on the military side is largely responsible for the current deficit crisis and the pressures for unprecedented domestic austerity. It represents a serious misjudgement of the nation's best interests. The long-term impacts on science, among many other endeavors, may be very damaging.

October 31, 1985

RECEIVED
NOV [illegible] 1985
COMMITTEE ON SCIENCE
AND TECHNOLOGY

Honorable Don Fuqua, Chairman
U.S. House of Representatives
Committee on Science and Technology
Suite 2321, Rayburn House Office Building
Washington, DC 20515

Dear Mr. Chairman:

You asked a number of questions to which you wished answers, as a follow-up to my testimony before the Science Policy Task Force on October 2, 1985. What follows are my answers to these questions.

1. Q: What do you see as the future roles for the Federal laboratories?

   A: These laboratories could continue to do what they are now doing. That is to say that they could continue to work on the same missions. They could also broaden their sponsorship and do more work for the private sector and maybe even the states. It is almost certain that they will have to define relationships with universities and industry that will be different from what they have been in the past. This is in line with what I said in my testimony was the new economic development mission. Also, there may be more international collaboration. The labs' educational role may increase. And, there is almost sure to be more technology transfer emphasis.

2. Q: How do smaller laboratories, in agencies such as U.S. Department of Agriculture and Veterans Administration, compare with the giants of NASA and DOE? Have they been through similar funding and mission changes?

   A: We really don't know that much about the small labs. They have not been studied as extensively as have been the larger laboratories. It is a good bet that because they are smaller, they are more vulnerable to swings in funding. They are probably more dependent on their agency sponsors and, therefore, less diversified. They probably have employees from a narrower range of disciplines. At least some of them are perhaps so small that they are submarginal in effectiveness, although this would be hard to document.

Syracuse Research Corporation Merrill Lane Syracuse, New York 13210-4080 Telephone(315) 425-5100

3. Q: If Federal laboratories are given national missions, will these missions supplement or supplant the missions of the agencies which fund the laboratories?

   A: These labs already have national missions in the sense that energy and space are national missions. The question is really one of national missions new to the agency and the country. How do the labs balance the new with the existing missions? Essentially, they must provide good services to agency sponsors. To the extent they have slack resources, they can deploy these resources toward new national missions. Where they are already fully committed, they may have to be provided with additional slots if they are to be redeployed to do something new. The only way to deal with this is by thinking of the labs as a national system. In a national system, those which are underutilized can be deployed to new missions as needs arise. We need an organization above the agencies and the labs to monitor this system as a whole. Only through a monitoring agency can this system be given any kind of guidance. OSTP would be the logical agency to play this monitoring role.

4. Q: Please comment on present and future technical staffing needs at the Federal laboratories in terms of quantity and quality.

   A: From previous studies, like the Packard Report, it can be said that quantity is not really a problem. The number of people presently in the system as a whole is sufficient for most needs. There are surges of needs (e.g., the energy crisis) where a lab may have to staff up quickly.

   Quality is undoubtedly a problem in certain cases. Attention has to be given to matters of incentives, as for example salaries. Also, flexibility in hiring is needed to bring on new professionals, thereby avoiding stagnation. In labs which have personnel ceilings, there could be a great problem of lack of fresh and innovative ideas from new people. There is also a need for stable funding for long term projects in laboratories, as there is in universities and industry.

I hope that these answers are responsive to your needs. If you have further questions, please do not hesitate to ask.

With best wishes.

Sincerely yours,

W. Henry Lambright

PANEL 2: SCIENCE IN THE U.S. DEPARTMENT OF DEFENSE

Mr. BROWN. Our next panel consists of Col. Donald I. Carter, U.S. Air Force, Acting Deputy Under Secretary of Defense for Research and Advanced Technology, U.S. Department of Defense, accompanied by Dr. Leo Young, Director, Research and Laboratory Management; and Dr. James A. Tegnelia, Acting Director, Defense Advanced Research Projects Agency.

They will tell us about research policies at DOD. We are happy to have you here, I think you can help us understand some of the fine detail.

[A biographical sketch of Colonel Carter and Dr. Young follow:]

COL. DONALD I. CARTER

Donald I. Carter is the Acting Deputy Under Secretary of Defense for Research and Advanced Technology. He is responsible for policy formulation, program development and program implementation of the Department of Defense Science and Technology program, a $5.5 billion annual effort. It is the largest multi-disciplined federally funded science and technology program in the U.S. involving about 53,000 people and over 70 DOD laboratories. He works primarily with the Congress, military services, universities, industry and counterparts in allied nations.

Colonel Carter was born in Attala County, Mississippi, on July 1, 1936. He attended Mississippi State University, graduating in 1958 with a Bachelor of Science degree in Civil Engineering.

His first Air Force assignment was at Little Rock Air Force Base, Arkansas, as the base bioenvironmental engineer. By 1960, he moved to Vanderberg Air Force Base, California, as a bioenvironmental engineer working with the Atlas, Titan and Minuteman strategic missile systems.

In 1964, Colonel Carter was named staff bioenvironmental engineer for the Aerospace Medical Division, Brooks Air Force Base, Texas. He served as liaison between biotechnology and hardware research and development organizations. He was assigned to Clark Air Base, Philippines in 1969 as a bioenvironmental engineer responsible for the Bioenvironmental Engineering Program for Air Force bases in the Philippines, Thailand and Taiwan.

Returning to the United States in 1971, Colonel Carter was assigned to Headquarters, U.S. Air Force, Washington, D.C. as staff officer and assistant for Medical Research and Standardization. In 1975, he became the Military Assistant to the Deputy Under Secretary of Defense for Research and Engineering (Research and Advanced Technology). In July, 1979, Colonel Carter was named Director of Research and Development for the Aerospace Medical Division and assumed his present position in 1984.

He is a graduate of the Squadron Officer School; Air Command and Staff College; and Air War College.

His decorations and awards include the Defense Superior Service Medal, Air Force Legion of Merit, Meritorious Service Medal with one oak leaf cluster, Commendation Medal, Vietnam Service Medal with five bronze service stars and the Republic of Vietnam Gallantry Cross with Palm.

DR. LEO YOUNG

Current position: Director for Research and Laboratory Management, Office of the Under Secretary of Defense for Research and Engineering (November 1981–present).

Previous affiliations: Naval Research Laboratory (1973–1981), Stanford Research Institute (1960–1973); Westinghouse Electric Corporation (1953–1960).

Education: Ph.D. (Electrical Engineering), The Johns Hopkins University, B.A. and M.A. (Mathematics, Physics), Cambridge University, England.

Publications: Authored, co-authored or edited 14 Books, 20 patents, more than 100 papers.

Professional Societies: President, IEEE, 1980; Fellow, IEEE, 1968; Fellow, AAAS, 1979; etc.

Visiting Professor/Lecturer: Stanford University, Stanford, California; Leeds University, England; University of Bologna, Italy; Technion, Israel; Technische Hochschule, Braunschweig, FRG; George Washington University, Washington, D.C.

STATEMENT OF COL. DONALD I. CARTER, U.S. AIR FORCE, ACTING DEPUTY, UNDER SECRETARY OF DEFENSE FOR RESEARCH AND ADVANCED TECHNOLOGY, U.S. DEPARTMENT OF DEFENSE, WASHINGTON, DC, ACCOMPANIED BY DR. LEO YOUNG, DIRECTOR, RESEARCH AND LABORATORY MANAGEMENT, U.S. DEPARTMENT OF DEFENSE, WASHINGTON, DC

Colonel CARTER. Mr. Chairman and members of the task force, I appreciate the opportunity to testify before this task force which has been specially established to hold hearings on science in the mission agencies and Federal laboratories.

Today I will describe our objectives for the DOD science and technology program, the role that it plays in the development and acquisition of material for the DOD, the relationship of S&T to the Soviet threat and the means by which the program is managed and executed in DOD.

Major developments in Soviet military capabilities pose new challenges to us. The Soviet military buildup, both quantitative and qualitative, has produced a major shift in the nuclear and conventional balance. The Soviet military posture has become increasingly more capable in its offensive orientation. The Soviets have significantly extended the global reach of their military forces, enhancing their ability to project influence and power, especially in the Third World.

Since 1981, substantial progress has been made toward ensuring that our military capabilities are strong enough to fulfill their critical purpose. The technology that provided the options for this progress was developed over the past two decades by the DOD S&T program in partnership with the technology community of our private sector.

We plan to continue reliance on the technology edge. It is the most viable of our options. We plan to continue to make full use of the in-house laboratories and the industrial sector. In addition, we will continue to strengthen our relationship with the university community by allocating to them a significant portion of the basic research program, by continuing our program of upgrading university research instrumentation, and by supporting efforts to increase scientific and engineering education in areas of interest to DOD.

The DOD science and technology program request for fiscal year 1986 is $5.3 billion which covers the combined Army, Navy, Air Force and Defense agencies programs. Of this amount, $971 million is for research and $2.6 billion is for exploratory development and $1.7 billion is for advanced technology demonstrations. The S&T program also encompasses the Strategic Defense Initiative and our fiscal year 1986 request for SDI is an additional $3.7 billion.

When Congress established the Office of Naval Research in 1945, DOD became the first Government organization to formally support basic research. Our commitment to research continued with the establishment of the Army Research Office, the Air Force Office of Scientific Research and the Defense Advanced Research Projects Agency.

Today we are but one of several major sponsoring agencies for basic research in the physical sciences and engineering along with NSF, DOE, and NASA.

There was a steady erosion in DOD sponsored research in the decade 1965 to 1975, both in absolute terms and as a percentage of the total Federal Government support for basic research. In constant dollars, DOD support for research in fiscal year 1975 was only one-half of what it had been in the midsixties.

We are attempting to recover to our 1965 level of effort. Similarly, as a percentage of the Federal Government's support for research, the DOD share fell from over 25 percent in the early 1960's to 11 percent in 1975, and has remained at that reduced level.

We employ directly 105,000, 3.6 percent of the Nation's scientists and engineers in our civilian and military work force. In addition, another 13 percent are directly linked to defense budgets and programs. We, therefore, have an important, although by no means dominant, stake in the quality and supply of the national pool of scientists and engineers. Other institutions and sectors of our economy cumulatively have an equal, if not greater, impact and leverage in working these problems.

Over the years, our program has supported the development of such crucial technologies as atomic energy and radar which have had a major impact on the very nature of warfare, the laser, superconducting devices, integrated circuits, intercontinental missiles, aircraft and missiles, command and control systems, and strategic and tactical surveillance.

Our S&T program is executed by teams of scientists and engineers working within the DOD, industries, and universities. Universities are the major performers of research, conducting about one-half of the effort. This is not surprising since universities are the Nation's primary resource for research. They are involved in a much smaller amount of applied research and development.

Our in-house laboratories are the key integrators of the S&T program and play a lead role in research and exploratory development. They help lead the search for new knowledge and concepts. The in-house laboratories provide analytical advice and technical services in planning DOD's R&D program. They provide the strong base of technical knowledge necessary to help make DOD a smart buyer.

Industrial participation in the program gives us access to the highly skilled work force and extensive facilities of our Nation's industries. Involvement of industry in the exploratory development and advanced technology demonstration programs also facilitate the transition of the technology to systems development and production.

The Deputy Under Secretary of Defense for Research and Advanced Technology's responsibilities are to provide the policy and guidance to be followed by the services in their execution of the program and to maintain oversight to ensure the productivity, strength, and vitality of the program. In executing these responsibilities my office serves as the DOD point of contact for the scientific community. Through our role as DOD's S&T focal point, we coordinate the program across the services, resolve technical differ-

ences arising in the separate service programs, and enhance the return on the S&T investments in defense.

The S&T program is planned, formulated, and executed by the three services, DARPA, and DNA. The process of defining what work needs to be done involves consideration and evaluation of the projected operational needs and the technological opportunities for meeting those needs. Many more programs are proposed than can be accommodated within our budget. The S&T programs must compete for funding with the other requirements for systems development, equipment acquisition, operations and maintenance, military construction, et cetera. We widely publicize our program requirements to potential performers.

Coordination is a significant element of planning and executing a research and development program. And we do this through several mechanisms including an extensive documentation center that provides information on planned, ongoing and completed programs for DOD units, defense contractors, and other interested Government agencies; through international agreements with our allies; and, in the domestic arena, through a series of formal and informal activities.

The transfer of the results of the S&T program is accomplished through many routes, depending upon the nature of the program. For basic and applied research, the dominant means is through publications in professional journals and reports. These are also made available through the established information sources such as the Defense Technical Information Center and the National Technical Information Service.

A more effective route to infuse the latest technology into DOD operations is through close collaboration between extramural and in-house laboratory researchers and with systems development.

As we look to the future, we see some areas which will demand our attention to insure technological advantage. Included are the needs for science and engineering education and laboratory modernization both university and in-house.

As I mentioned earlier, the defense industry employs about 17 percent of the scientists and engineers in the Nation. A recent National Science Foundation study projects shortages exceeding 10 percent of the work force by 1987 in disciplines particularly important to DOD: aeronautical engineers, computer specialists, and electrical engineers.

We take an active role in S&E education. Our direct funding of university research to develop new technology also contributes to S&E education. On average, $1 million of $6.1 research funding in a university provides financial support for approximately 10 to 15 graduate students. On that basis, our research program provided financial assistance for well over 4,000 graduate students in 1984.

In 1983, we initiated a new program to provide funding dedicated to the purchase of some of the more expensive S&T equipment items required to modernize university laboratories. The University Research Instrumentation Program is a 5-year, $150 million program to provide items of equipment in the $50,000 to $500,000 price range which can be used in research of primary concern to the services. In our first 3 years, we awarded $90 million in over 650 grants to 152 universities in 47 States. Awards for the next incre-

ment of $60 million for fiscal year 1986 and fiscal year 1987 will be announced next spring as the result of the evaluation of proposals due in by November 1985.

In fiscal year 1986, we will initiate a new DOD-university research initiative. $25 million has been requested in the research program for two major thrusts.

The first thrust includes fellowship, assistantship, exchange scientist and instrumentation programs. We will involve our in-house laboratories and scientific research offices with the objective of enhancing the Nation's science and engineering capability and, at the same time, strengthening the interaction between in-house laboratory and university researchers.

The second thrust of this new initiative will be the initiation of multidisciplinary science and engineering research programs in a number of high risk, potentially high payoff areas such as materials, fluid mechanics, aeronautics, biotechnology, communication networks, computer science, and microelectronics. We have high hopes for this new start.

As a matter of fact, the House-Senate Conference Committee on authorization increased our $25 million request to $100 million total.

Mr. BROWN [presiding]. We still have two committees to go through.

Colonel CARTER. Thank you, Mr. Chairman.

[The prepared statement of Colonel Carter follows:]

HOLD UNTIL RELEASED
BY THE SUBCOMMITTEE

THE DEPARTMENT OF DEFENSE STATEMENT ON SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

By
COLONEL DONALD I. CARTER, USAF
ACTING DEPUTY UNDER SECRETARY OF DEFENSE
FOR RESEARCH AND ADVANCED TECHNOLOGY

BEFORE THE TASK FORCE ON
SCIENCE POLICY OF
THE COMMITTEE ON SCIENCE AND TECHNOLOGY OF
THE UNITED STATES HOUSE OF REPRESENTATIVES
99th CONGRESS, FIRST SESSION

2 OCTOBER 1985

Mr. Chairman and Members of the Task Force:

1. INTRODUCTION

I am grateful for the opportunity to testify before this Task Force which has been specially established to hold hearings on "Science in the Mission Agencies and Federal Laboratories."

Today I will describe our objectives for the DoD Science and Technology (S&T) program, the role that it plays in the development and acquisition of materiel for the DoD, the relationship of S&T to the Soviet threat and the means by which the program is managed and executed in DoD.

America's paramount national interests are peace, freedom and prosperity for ourselves and for others around the world. Supporting these interests is our desire for an international order that encourages self determination, democratic institutions, economic development and human rights.

In an increasingly complex world, the fulfillment of U.S. national interests requires military strength because the international order we envision cannot be guaranteed in the face of the numerically superior forces of our adversaries. Major developments in Soviet military capabilities pose new challenges to our defense policy:

- The Soviet military buildup, both quantitative and qualitative, has produced a major shift in the nuclear and conventional balance.

- The Soviet military posture has become increasingly more capable in its offensive orientation.

- The Soviets have significantly extended the global reach of their military forces, enhancing their ability to project influence and power, especially in the third world.

Since 1981, substantial progress has been made toward ensuring that our military capabilities are strong enough to fulfill their critical purpose. Current programs are building more ready conventional forces, more modern nuclear forces, more modern command and control systems, well equipped tactical ground and air forces and greatly improved maritime forces. The technology that provided the options for this progress was developed over the past two decades by the DoD S&T program in partnership with the technology community ot our private sector.

Technology, however, is a perishable commodity. Our task is to sustain progress so that we will have the technical options available to provide future commanders and troops with the tools to accomplish difficult and uncertain tasks in many potential combat environments. However, the lead times from ideas to military hardware are long. Therefore, it is important that we conduct a strong and vigorous S&T program now as an investment in the future well being of the country's security.

The Soviets also recognize the importance of technologically superior weapons and have given their Research, Development, Test and Evaluation (RDT&E) program high funding priority. This heightens the challenge to the United States in that we depend heavily on qualitatively superior weapons to provide an edge over numerically superior adversaries.

In the technology race we do have an advantage not available to the Soviets. In addition to the efforts undertaken in the DoD S&T Program, the U.S. possesses a strong, viable and innovative private sector which is available to do sound research and

development both on its own behalf and in support of the defense sector. The combined efforts of these participants have provided us the lead in most militarily significant technologies but it is important to continue a large and vigorous DoD S&T program to preclude progressive erosion of our position.

We plan to continue reliance on the technology edge. It is the most viable of our options and we must increase our investment to maintain our technological lead. We plan to continue to make full use of the in-house laboratories and the industrial sector. In addition, we will continue to strengthen our relationship with the university community by allocating to them a signiticant portion of the basic research program, by continuing our program of upgrading university research instrumentation and by supporting efforts to increase scientific and engineering education in areas of interest to DoD.

2. THE DOD SCIENCE AND TECHNOLOGY PROGRAM

A. Funding

The S&T program request for FY 1986 is $5.3 billion which covers the combined Army, Navy, Air Force and Defense Agencies programs. Table I is a summary of FY 1985 amounts and our request for FY 1986. Table I includes Research (6.1), Exploratory Development (6.2) and Advanced Technology Development (6.3A).

The S&T program encompasses the Strategic Defense Initiative (SDI). I have outlined the SDI amounts in Table I for information purposes.

There is no doubt that the technological superiority upon which our national security depends is being challenged as never

before. Our only hope of meeting this challenge is through the continued superior achievements in the DoD S&T program by academic, industrial and governmental organizations.

TABLE I
SCIENCE AND TECHNOLOGY PROGRAM
(Dollars in Millions)

	FY 1985	FY 1986
Research	861	971
Exploratory Development	2,281	2,555
Advanced Technology Development	1,377	1,748
TOTAL SCIENCE AND TECHNOLOGY	4,499	5,274
Strategic Defense Initiative	1,389	3,713

Note: Numbers may not add due to rounding

When Congress established the Office of Naval Research in 1945, DoD became the first government organization to formally support basic research. Our commitment to research continued with the establishment of the Army Research Office, the Air Force Office of Scientific Research, and the Defense Advanced Research Projects Agency.

Today we are but one of several major sponsoring agencies for basic research in the physical sciences and engineering along with NSF, DoE, and NASA. The major sponsor of scientific research is the Department of Health and Human Services which emphasizes the areas of medical and biological research. Figure 1 depicts the current distribution.

There was a steady erosion in DoD sponsored research in the decade 1965 to 1975; both in absolute terms and as a percentage of the total Federal government support for basic research. Figure 2 shows that, in constant dollars, DoD support for research in FY 75 was only one half of what it had been in the mid-sixties. Similarly, Figure 3 shows that as a percentage of the Federal government's support for research, the DoD share fell from over 25 pecent in the early-sixties to only 11 percent in 1975, and has remained at that reduced level.

B. Personnel

There are approximately 2.9 million scientists and engineers (S&E's) at work in the nation. We employ 105,000 (3.6%) of them in our civilian and military workforce of 3.1 million people. Of these S&E's approximately 78,000 are civilians -- 72 percent of whom are engineers -- 27,000 are military officers.

DoD also employs almost 740,000 technicians, 22,000 of whom are civilians. About 715,000 technically qualified individuals are in the military enlisted force; they account for 40 percent of total enlisted personnel.

Beyond the 105,000 civilian and military S&E personnel directly employed by the Department, another 13 percent of the nation's total S&E workforce is directly linked to Defense budgets and programs. We, therefore, have an important, although by no

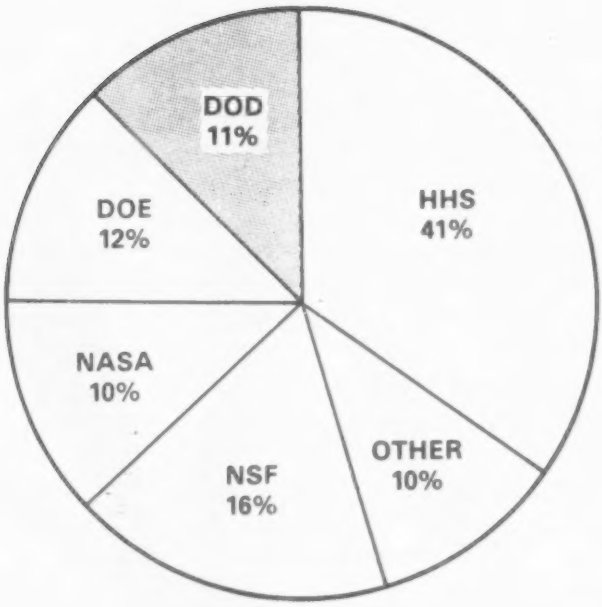

FIGURE 1 - DISTRIBUTION OF BASIC RESEARCH FUNDS BY AGENCY (1985 ESTIMATE)

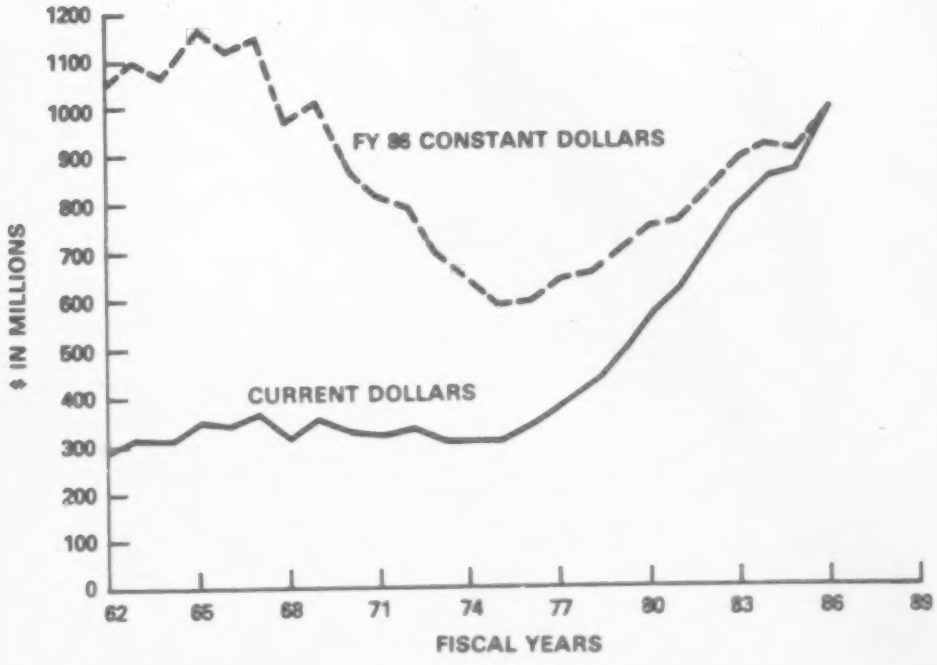

FIGURE 2 - DoD SCIENCE AND TECHNOLOGY TREND CURRENT AND CONSTANT DOLLARS RESEARCH (6.1)

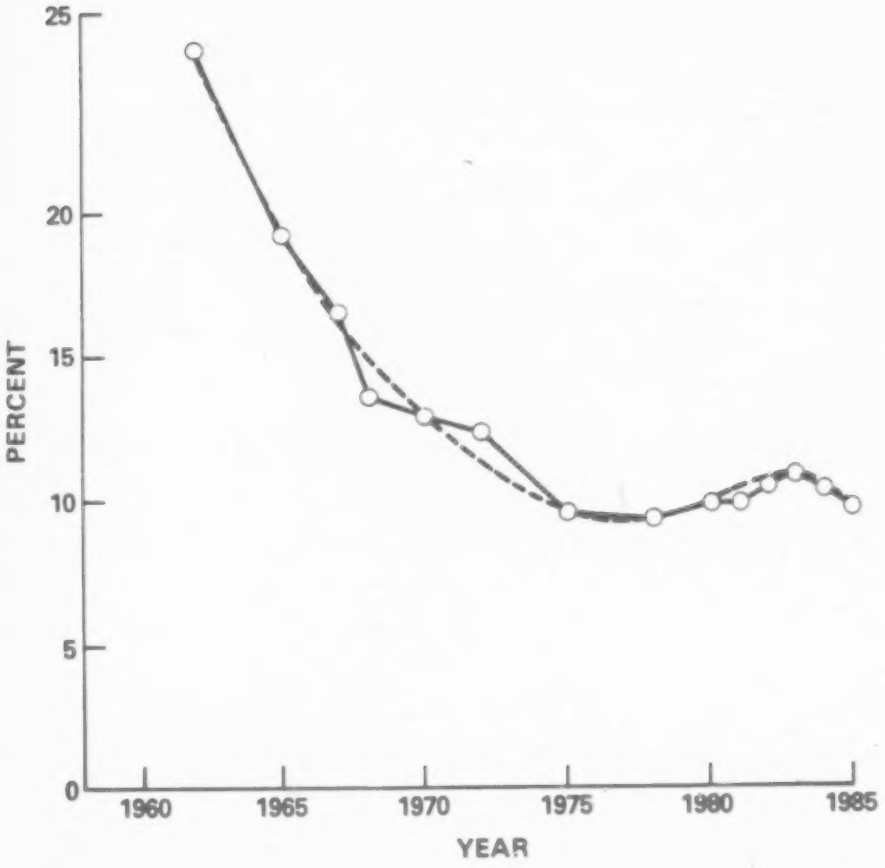

FIGURE 3 - PERCENTAGE OF TOTAL FEDERAL GOVERNMENT SUPPORT FOR RESEARCH PROVIDED BY DoD (6.1)

means dominant, stake in the quality and supply of the national pool of scientists and engineers. Other institutions and sectors of our economy cumulatively have an equal, if not greater, impact and leverage in working these problems.

C. Technical Areas

The DoD Science and Technology program covers a wide range of projects and programs. These projects and programs span the spectrum of military activities and form the basic foundation for our future military forces. Table II gives examples of the technology areas represented in the program.

TABLE II
SCIENCE AND TECHNOLOGY PROGRAM
TECHNOLOGY AREAS

- Space Technology
- Computer Sciences
- Electronics
- Surveillance
- Command and Control
- Communications
- Propulsion
- Aerodynamics
- Night Vision
- Chemical and Biological Defense
- Materials and Structures
- Medical and Life Sciences
- Others

The military Service research offices (ARO, AFOSR and ONR) play a major role in the interface between the operational-capability-driven military needs and the discipline-oriented university research community. Research required to support the DoD mission is concentrated in the twelve classical disciplines shown in Table III.

TABLE III
RESEARCH DISCIPLINES

Physics, Radiation Sciences, Astronomy, Astrophysics	Aeronautical Sciences
	Oceanography
Electronics	
	Terrestrial Science
Chemistry	
	Atmospheric Sciences
Mathematics and Computer Sciences	Biological and Medical Sciences
Mechanics and Energy Conversion	
Materials	Behavioral Sciences

D. Accomplishments

During World War II, our program supported the development of such crucial technologies as atomic energy and radar which have had a major impact on the very nature of warfare. Research during the 1950's and 1960's led to the maser and laser, superconducting devices, integrated circuits, intercontinental missiles, computerized weaponry, vastly improved communication systems, and advances in medical science. Research in the 1970's and early 1980's has made major contributions to aircraft and missile

technology, command and control systems, strategic and tactical surveillance, and has provided the foundation for the Strategic Defense Initiative.

The development of the TRIDENT submarine's advanced echo sounder provides a good illustration of the effectiveness of our S&T program in integrating the effort of universities, in-house laboratories, and industry. A research program initiated in 1963 at Brown University developed the concept of parametric sonar based on non-linear acoustics. Programs at Brown University and the Applied Research Laboratory at the University of Texas turned the concept into hardware. Together with in-house laboratory personnel, Raytheon developed the operational system for the TRIDENT.

The S&T program is woven into the fabric of national life in a pervasive though not always obvious way. The very-high-speed integrated circuit (VHSIC) program now in progress will have a major effect on the electronics industry; VHSIC will eventually enter our lives in ways that will make the wonders of children's talking toys and personal computers seem elementary by comparison. Similarly, work on parallel arrays may profoundly affect the next generation of large computers.

E. Performers

Our S&T program is executed by teams of scientists and engineers working within the DoD, industries, and universities. The funds allocated to the three major performers are shown in Figure 4 for both the research and the total S&T program.

Universities are the major performer of research, conducting about one-half of the effort. This is not surprising since universities are the nation's primary resource for research.

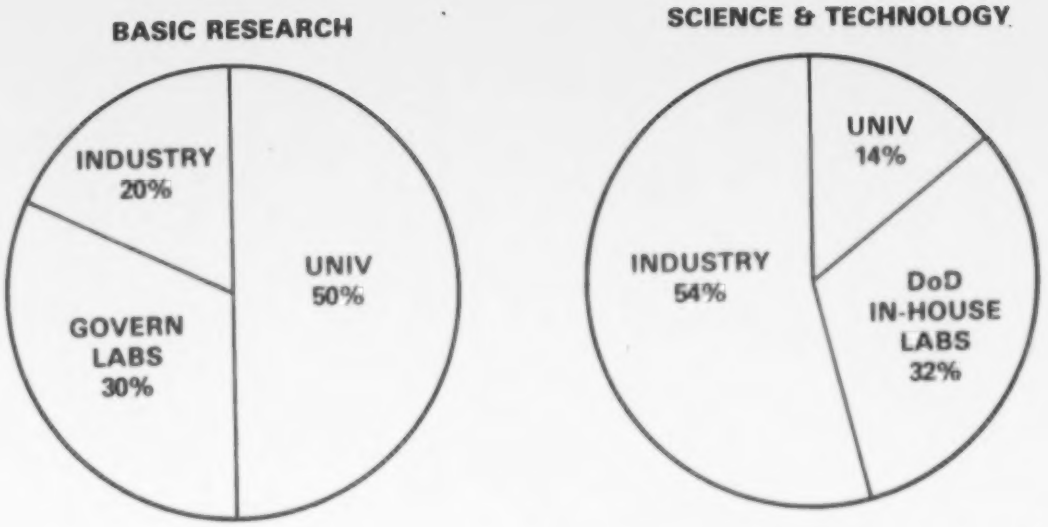

FIGURE 4 - PERFORMERS OF DoD SCIENCE AND TECHNOLOGY

They are involved in a much smaller amount of applied research and development. Their involvement in DoD programs is critical to the achievement of our technology objectives. Close ties with the university community also act to strengthen the in-house and industrial components of the program. A further benefit is that gained through the education of future scientists and engineers in disciplines essential to DoD.

We look to our in-house laboratories to be the key integrators of the S&T program and to take a lead role in research and exploratory development. They help lead the search for new knowledge and concepts. The in-house laboratories provide analytical advice and technical services in planning DoD's R&D program. These laboratories must maintin high scientific and technical competence so that outside technical advice can be evaluated and put into proper perspective in the decision making process. They provide the strong base of technical knowledge necessary for effective assistance in acquiring new systems; that is, to help make DoD a "smart buyer." One of the laboratories' more basic responsibilities is the maintenance of a highly competent technical staff to keep DoD and the Services informed of the latest scientific and technical opportunities pertinent to defense needs.

Industrial participation in the program gives us access to the highly skilled workforce and extensive facilities of our nations' industries. Involvement of industry in the Exploratory Development and Advanced Technology Demonstration programs also facilitate the transition of the technology to systems development and production.

F. Program Management

(1) Management

The Deputy Under Secretary for Research and Advanced Technology is responsible for the DoD Science and Technology Program. My responsibilities are to provide the policy and guidance to be followed by the Services in their execution of the program and to maintain oversight to insure the productivity, strength, and vitality of the program. In executing these responsibilities my office serves as a principal scientific advisor to the Under Secretary of Defense for Research and Engineering, and as the DoD point of contact for the scientific community. Through our role as DoD's S&T focal point, we can coordinate the program across the Services, resolve technical differences arising in the separate Service programs, and enhance the return on the S&T investments in defense.

(2) Program Formulation

With overall guidance from the Office of the Secretary of Defense, the S&T program is formulated by the three Services and DARPA. The process of defining what work needs to be done involves a consideration and evaluation of the operational needs and the technological opportunities for meeting those needs. The needs are derived through a comparison of the future, projected threat with planned U.S. capability and doctrine. Programs are developed to address these needs based on the exploitation of technology opportunities. Addressing long-term, more general requirements and providing the basis for future technology advancement requires the development of new research efforts. Examples of current research efforts include:

signature suppression, less vulnerable communications, space propulsion, improved visibility in degraded environments, elimination of corrosion, advanced energy beaming weapons, artificial intelligence, robotics, and microelectronics. Many more programs are proposed than can be accommodated within the Services' budget. The S&T programs must compete within the Service with the other requirements for systems development, equipment acquisition, operations and maintenance, facilities, etc.

The necessity of supporting a strong S&T program, while addressing other priorities was underscored by the Secretary of Defense in 1984.

> "As we allocate resources to the short term goals, however, we must not sacrifice our national security... We must provide now for the technology that will permit us to acquire, operate and support weapon systems that will be entering our inventory 15-20 years from now. To do otherwise would jeopardize our security in the future since we are relying on the leverage provided by deployed systems which utilize superior technology."

(3) Communication of Requirements

We widely publicize our program requirements. Formal solicitations are included in the Commerce Business Daily. Service research offices issue Broad Agency Announcements. Laboratories and commands provide information briefings to industry. The research community is reached through presentations at professional societies and other national and regional forums.

(4) Program Review

We use a three-tier review process to guide the prioritization of the S&T program, ensure scientific and technical adequacy within the program, and ensure cross-Service coordination.

The S&T investment strategy of each Service is reviewed annually. I chair this review which covers: investment rationale, program technology thrusts, resource allocation (people and funds), and accomplishments. This review provides a top-down examination of S&T programs at the laboratory level.

Science and Technology reviews are structured to provide a middle management review of the Services' S&T programs in specific areas such as Materials and Structures, Environmental Sciences, Computer Software and Systems, etc. These reviews are conducted by my office Directors. At such a review, mid-level managers from each of the Services present the S&T program content in the area with an emphasis on direction at the project level. Major attention is given to quality, program milestones, potential payoffs and technology transition.

In-depth Topical Reviews of the Service's programs in focused areas are conducted as required. These reviews cover the DoD-wide effort in focused areas such as gun and missile propulsion, jet engines, electron devices, chemical defense, etc. The reviews are conducted by staff specialists in my office and feature presentations by laboratory scientists and engineers on the technical programs in the particular area. These reviews provide an in-depth technical assessment of the area and are a valuable coordination tool.

(5) Coordination

Coordination is a significant element of planning and executing a research and development program. We are concerned that we do this well to ensure the maximum exchange of technical information, to preclude unwarranted duplication of effort and to facilitate management and investment decisions. To this end we maintain an extensive documentation center that provides information on planned, on-going and completed programs for DoD units, defense contractors, and other interested government agencies. This is supplemented by other activities.

The nation's defense is based on an alliance concept and it is important that appropriate exchanges be conducted among our Allies. A major portion of Allied coordination is accomplished via bi-lateral and multi-lateral agreements tailored to the needs of participating countries. In the science and technology program area, particularly effective coordination is carried out in The Technical Cooperation Program, the NATO Defense Research Group and the NATO Advisory Group on Aeronautical Research and Development. In our view, the international coordination in areas of defense technical interest are extensive and well done.

In the domestic arena we are engaged in a series of formal and informal activities to achieve coordination goals. Internal to DoD we continuously review the various aspects of the program to optimize our return on investment and to determine programs suitable for joint execution. In the interagency arena formal arrangements exist with other government agencies such as NASA and DoE in areas of mutual interest. Also, there are frequent contacts with the National Science Foundation, the National Academies of Science and Engineering and the university community. And finally, as in the case of all organizations doing

R&D, we are engaged in active sponsorship of and participation in symposia, conferences and meetings in the research and development field.

G. Technology Transfer

The transfer of the results of the S&T program proceeds through many routes, depending upon the nature of the program. For basic and applied research, the dominant means is through publications in professional jounals and reports. These are also made available through the established information sources such as the Defense Technical Information Center and the National Technical Information Service.

A more effective route to infuse the latest technology into DoD operations is through close collaboration between extramural and in-house laboratory researchers and with systems development. Such collaboration provides the immediate benefit to DoD of results and breakthroughs achieved on sponsored programs. In recognition of the importance of this mechanism we are taking steps to strengthen the laboratory-university relationships; partly through the University Research Initiative which will be discussed later.

3. CHALLENGES AND RESPONSES

As we look to the future, we see some areas which will demand our attention to insure technological advancement. Foremost of these are the needs for science and engineering education and laboratory (both university and in-house) modernization.

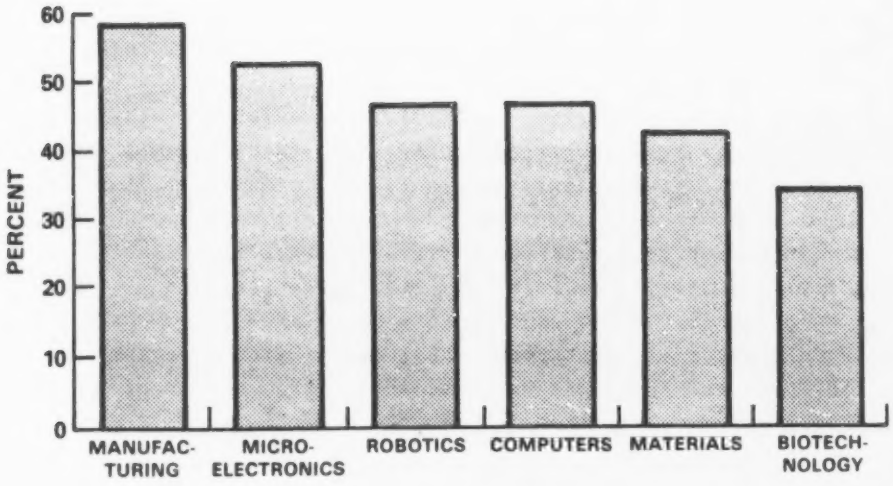
A. Education

The U.S. defense industry is a major employer of the scientists and engineers trained by U.S. universities and colleges. One out of six (17%) scientists and engineers is either directly employed by DoD or works for a defense industry. A recent National Science Foundation (NSF) study projects rapid growth and shortages exceeding 10 percent of the workforce (by 1987) in disciplines particularly important to DoD: aeronautical engineers, computer specialists, and electrical/electronic engineers.

The prospects for attracting greater numbers of outstanding students into careers in science and engineering in DoD are clouded by a number of important factors including:

- Graduate schools, particularly in engineering and related disciplines are having difficulty recruiting and retaining U.S. citizens. The distribution of foreign students in emerging engineering areas is illustrated in Figure 5. Reasons for the decline in the graduate education of U.S. citizens include the lure of industry with existing pay differentials, the increasing cost of graduate school, and the decline in federal financial assistance.

- The number of Ph.D.'s in engineering awarded to U.S. citizens by U.S. universities declined steadily throughout the 1970's and early 1980's, with a net decline of 42 percent between 1968 and 1982. Nearly half of all engineering Ph.D.'s now are awarded to foreign nationals. Foreign engineering Ph.D.'s, even if they remain in the U.S., generally cannot obtain U.S. security clearances and are thus not available for direct DoD employment.



SOURCES. NATIONAL SCIENCE FOUNDATION AND AMERICAN COUNCIL ON EDUCATION

FIGURE 5 - FOREIGN DOCTORAL STUDENTS IN EMERGING ENGINEERING AREAS: 1984

The ability of the United States to maintain superiority in broad areas of science and technology will largely depend on how well universities and colleges are able to recruit and train new scientific and engineering talent. It is especially important that the DoD take an active role in S&E education to insure the future availability of trained personnel.

The direct funding of university research meets our requirements for new technology and contributes to the S&T education program. A 1980 Navy study suggests that, on average, a million dollars of 6.1 university research funding provides financial support for approximately 10-15 graduate students. On that basis, our research program provided financial assistance for well over 4000 graduate students in 1984. In addition, the combination of research contracts and instrumentation programs provides a university research environment that is essential to retain university faculty and to attract graduate students.

During the past decade, DoD has initiated numerous "people-oriented" programs designed to increase the supply of qualified technical personnel, both uniformed and civilian, and to attract exceptional candidates into careers in areas of particular importance to DoD. The complete set of programs is extremely diverse, ranging from secondary school level through undergraduate and graduate school. Some are also designed for postgraduates and university faculty. These formal programs are supplemental to DoD's research programs.

B. University Research Instrumentation

There has been a growing realization among the scientific and university communities, and in state and Federal government agencies and the Congress, that the condition of research instrumentation in U.S. universities declined significantly during the 1970's.

INTENTIONAL BLANK

In 1983 the DoD initiated a new program to provide funding dedicated to the purchase of some of the more expensive S&T equipment items required to modernize university laboratories. The University Research Instrumentation Program is a five-year, $150 million program to provide items of equipment in the $50,000 to $500,000 price range which can be used in research of primary concern to the Services. The program is funded at $30 million per year through FY 87, and approximately equals the annual funding level for equipment items which are routinely included in research contracts with universities. In our first three years, we awarded $90 million in over 650 grants to 152 universities in 47 states. Awards for the next increment of $60 million for FY 86 and FY 87 will be announced next spring as the result of the evaluation of proposals due in by November 1985.

C. DoD-University Research Initiative

In FY 1986, we will initiate a new DoD-University Research Initiative. This program will address some of the widespread concerns about the infrastructure of science and technology in the United States and its relation to a stronger national defense and national economy. Twenty-five million dollars has been included in the Research program, approximately $6 million for each of the three Services and DARPA. We plan to grow this program in the near term. This new start will consist of two major thrusts.

The first thrust includes fellowship, assistantship, exchange scientist and instrumentation programs. The first three, "people" programs, will involve our in-house laboratories and scientific research offices with the objective of enhancing the nation's science and engineering capability and, at the same time, strengthening the interaction between in-house laboratory and university researchers. Additional funding for instrumentation has been included in this initiative.

The second thrust of this new initiative will be the initiation of multidisciplinary science and engineering research programs in a number of high risk, potentially high payoff areas such as materials and structures, fluid mechanics, aeronautics, biotechnology, communication networks, computer science, microelectronics, and optical materials. The intent is to support programs which concentrate talent to achieve the "critical mass" required to accelerate research achievements. These multidisciplinary programs will be managed through a Tri-Service and DARPA committee which will provide close coordination with DoD and a single point of focus for the universities.

We have high hopes for this new start.

4. CONCLUSION

The DoD is supporting a vigorous Science and Technology program which is designed to assure the continued technological superiority of our defense systems. The program is planned to meet our critical needs and exploit technological opportunities. From basic research through development, our program successfully integrates the efforts of the university, industrial and in-house laboratory performers. Through attentive management and careful coordination we are maximizing the return on our S&T investment.

We see areas which require our concern and attention to maintain the momentum of our S&T program. We are addressing the critical areas of science and engineering education and laboratory modernization.

5. BIBLIOGRAPHY

The following studies are representative of the many which have been done in the last ten years on topics related to this presentation:

Mr. BROWN. All right, did you wish to add anything, Dr. Young?

Dr. YOUNG. No; I think that is a pretty complete summary, perhaps I can help answer questions.

Mr. BROWN. Dr. Tegnelia.

[A biographical sketch of Dr. Tegnelia follows:]

DR. JAMES A. TEGNELIA

Dr. James A. Tegnelia was born on July 8, 1942 in Charleroi, Pennsylvania. He attended public schools in Monessen, Pennsylvania and received his B.S. in Physics from Georgetown University and M.S. in Business Administration from George Washington University. He possesses a Ph. D. in Physics from Catholic University.

Dr. Tegnelia was appointed Principal Deputy/Acting Director DARPA, September 9, 1985. Dr. Tegnelia is currently serving as the Acting Deputy Under Secretary of Defense for Tactical Warfare Programs and the Assistant Under Secretary of Defense for Conventional Initiatives and Director, Conventional Initiatives Program Coordination Directorate located in the Office of the Under Secretary of Defense for Research and Engineering. Dr. Tegnelia manages the tactical weapons program for the Department of Defense. His duties include allocating development resources, overseeing the needs of the military services in new program initiatives, and managing the acquisition of tactical programs. He and his staff of 61 people answer to the Under Secretary of Defense for Research and Engineering on programs totaling over $75 billion. He is also responsible for facilitating integrated program management of several joint Service development and acquistion programs involving the interdiction of enemy follow-on forces. He has represented the Under Secretary on several Joint Chiefs of Staff studies and has been a member of several Defense Science Boards.

Prior to assuming his current duties, Dr. Tegnelia was Director, Tactical Technology Office (TTO) within the Defense Advanced Research Projects Agency (DARPA). He was responsible for a wide range of developments related to tactical warfare and directed the research activities of approximately 22 scientists and engineers. The TTO programs encompassed approximately $221 million of research and development funds and covered the spectrum of technologies in air, land, and ocean warfare. While at DARPA, Dr. Tegnelia held various positions from 1976 to 1983 and as a result of his exceptional performance in these increasingly responsible positions, he was honored with the Presidental Meritorious Executive Rank Award in December 1982.

In previous positions in the Defense Department, Dr. Tegnelia served as Director of the Advanced Concepts Team of the U.S. Army Night Vision Laboratory from 1971 through 1976. During this period, he was responsible for the development of advanced aircraft, tank, missile and individual soldier night vision aids. While serving in this capacity, he initiated development of standardized infrared sensor modules and tank thermal weaponsights. Dr. Tegnelia received the Civilian Meritorioius Service Award for this work.

From 1968 to 1970, Dr. Tegnelia served in the U.S. Army, first with the Project Manager Office for Night Vision and later with the Army Concepts Team in Vietnam. These positions were concerned with test and evaluation management of advanced senosrs and with the suitability of night vision equipment for employment in Southeast Asia. Dr. Tegnelia received the Bronze Star Medal and the Army Commendation Medal for service while in the Army.

He is a member of the Society of Sigma Xi, the Honorary Research Society.

Dr. Tegnelia is married to the former Sandra George of Martin, Tennessee and they have two children, a daughter, Abby and a son, Ryan.

REPRESENTATIVE PROGRAM RESPONSIBILITIES

Current Activities:

All tactical weapons programs in DoD; JSTARS (Targeting Radars); JTACMS (Ballistic Missiles); Tactical Cruise Missiles; Submunition Development; Surveillance Platform Development; RPV's; and Tactical Fusion.

Past Experience:

Assault Breaker; Pave Mover; Tactical "Stealth;" Advanced Cruise Missiles; Forward Swept Wing; RPV's; Focal Plane Arrays; Anti-Armor Submunition; Terminal Guidance; Tank Development; Anti-Tank Missiles; Armor and Warhead Development; Cruise Missile Engines; Night Vision Devices; Fleet Air Defense Development; Torpedo Technology Development; and Acoustic and Non-Acoustic ASW Technology.

STATEMENT OF DR. JAMES A. TEGNELIA, ACTING DIRECTOR, DEFENSE ADVANCED RESEARCH PROJECTS AGENCY, U.S. DEPARTMENT OF DEFENSE, WASHINGTON, DC

Dr. TEGNELIA. Sir, I have prepared a summary statement for you that can be inserted to the record and——

Mr. BROWN. It will be.

Dr. TEGNELIA. For the sake of time, maybe you would like to go to your questions.

Mr. BROWN. I am sorry.

Dr. TEGNELIA. In the sake of time, I won't read that or try to summarize it so you can go to the questions.

Mr. BROWN. You don't want to summarize any of it?

Dr. TEGNELIA. No, sir.

Mr. BROWN. We generally use the time you summarize to think about what you said.

Dr. TEGNELIA. If you would like me to, I will summarize.

Mr. BROWN. Would you summarize in about 4 or 5 minutes, so I can have a chance to——

Dr. TEGNELIA. Sorry to break protocol. Let me take just a few minutes first of all to do two things. The first one is to describe what the Defense Advance Research Projects Agency is, and then the second thing is to tell you a little bit about what some of our research is and give you some kind of feeling for what it is we try to do.

First of all, let me be very clear about the fact that DARPA is not a research laboratory organization. Its total staff is about 160 people of which 90 or so are technical individuals, the remainder of the staff are administrative support and contract support and that type of thing. We have a budget of approximately $700 million a year, which is the responsibility of those 70 or so professionals.

We also are an expert organization which reports directly to the Under Secretary of Research and Engineering and to the Secretary of Defense. We do not report to any of the service organizations or service laboratories. So we are the analog, if you would, of an expert research and development activity.

I mentioned to you the fact that our budget is about $750 million. It is broken up approximately in some of data that I have provided to you, into about two-thirds of what I would consider to be applied research and technology, activities associated with tactical warfare programs, smart weapons, aeronautical research, that type of thing, and also the remaining one-third is associated with what I would consider to be basic science. Now, about $100 million of that $700 million goes to the University community and, to give you just one small piece of information, out of that one hundred million dollars, for every approximately 200,000 dollars' worth of research that we apply to the universities, we expect to have a Ph.D. also graduate as a side benefit. So, we represent about 500 new Ph.D.'s per year coming out of our research.

Let me turn now to some of the thrusts that DARPA is currently working on and use some of those thrusts to give us a little idea about how it is that we operate.

We are currently discussing the opportunity for what we consider to be a space plane, TAV, trans-atmospheric vehicle. The idea is

to build an aircraft which would take off from a runway like Dulles, be able to reach orbital speeds from one single aircraft without use of booster rockets or anything like that, so it would be literally a follow-on to the Concorde or SST or the Shuttle. Now, we believe that the country is getting very close to the kind of technology that it would be necessary to be able to build such a craft and so we are now working with first of all the three services in the Department of Defense and with NASA to be able to define the technology activities which would be necessary to make such a vehicle possible. To give you an example of that, you can imagine that in order to build a vehicle that would withstand escape velocity puts tremendous pressure on things like materials and structures. It will require new propulsion, aerodynamics techniques and also require what I would consider to be fairly difficult control techniques to be able to make sure that you can control the craft in flight. So we use an objective like that, to build an aircraft that could go into orbit, to drive our technology base pursuits so that our techno' gists understand the goals to which their research is oriented.

That is one example. The other example that we have spent a bit of time on is an area called strategic computing. The objective of the Strategic Computing Program is fairly straightforward to elucidate. That is, over the last, say, 25 years, the United States has had its computers increase their processing speed by about four orders of magnitude. It is going to be very difficult to continue that rate of growth. We basically did that over the last 40 years by increasing our capability in integrated circuits and that type of thing. We are going to reach the limit of what we can do with just doing it at the device level. So we are looking at new architectures for computers which will be able to let the data be processed in ways which will be faster than the current one calculation at a time method the way computers operate. That way we think we can continue the growth of the number of operations, that these computers can do—the same growth we have had over the last 20 years—and keep U.S. lead in information processing technology and computer sciences.

By way of summary, that new computer program is one where we have put very large amounts of money into university base, to have the universities continue to give us flexible new ideas in the area of computer sciences, material sciences, and the like, so that the Department of Defense has new innovative historic approaches to next—generation defense equipment. That in summary is the mission of the Defense Advance Research Project Agency.

[The prepared statement of Dr. Tegnelia follows:]

DEFENSE ADVANCED RESEARCH PROJECTS AGENCY

STATEMENT

BY

DR. JAMES A. TEGNELIA

ACTING DIRECTOR

BEFORE THE TASK FORCE ON SCIENCE POLICY

OF THE COMMITTEE ON SCIENCE AND TECHNOLOGY

OCTOBER 2, 1985

I. Introduction

Mr. Chairman and Members of the Task Force:

Thank you for the opportunity to present DARPA's perspective of its role as a Mission Agency which supports a significant amount of basic and applied research. The Task Force's objective of clearly defining the issues and options in the Government's role in supporting research is certainly necessary. In today's environment technology dominates national economic and security well-being, but the research underlying this technology has become very expensive and its support is provided in large measure by the Federal Government.

II. DARPA History and Charter

DARPA was created in 1958, in part as a reaction to the launching of Sputnik. Its creation also was a realization of the need for an organization within DoD to formulate and execute research and development (R&D) projects which expand the frontiers of technology beyond the well-identified requirements or missions of the military services and their laboratories. DARPA's programs encompass a wide range of scientific disciplines which address the full spectrum of the anticipated security needs of this nation.

DARPA's function resembles that of corporate research in private industry. Its programs focus on scientific investigations and proof-of-concept demonstrations of revolutionary products for use in future strategic, tactical, rapid-deployment, and sea-power scenarios. The Agency explores the possible military benefits of new and unconventional concepts and technologies for all Services, without specific role or mission limitations.

DARPA's investment strategy is guided by DoD's responsibility to maintain technological leadership in defense capabilities. Although R&D projects in advanced technologies often are high-risk, DARPA's role is to assume these risks (with the clear possibility of failure) when it is convinced that, if the technology succeeds, a breakthrough advancement in military capability results. In a very real sense, DARPA is a venture capital organization which supports high-risk, high-payoff science and technology that requires five to ten years or more to mature, i.e., well beyond the time-scale that private venture capital expects technological success, let alone operation at a profit, to justify upfront investment in research concepts.

III. Impact of DoD and DARPA-Supported Research

Time does not permit justice to this factor; however, several premier items serve as reminders of the impact of DoD's research endeavors on both national security and economic growth. For example, although the invention of the integrated circuit (IC) did not occur under a specific DoD effort, the activity leading up to it was spurred by the DoD search for a "molecular electronics" to reduce size and power and increase reliability of electronic systems. Subsequent to invention of the IC, DoD research played a major role in the early, expensive, high-risk, high-payoff stages

(1960-1965) of IC development. Similarly, nickel-based superalloys developed by DoD made possible today's military and commercial jet engines. Significant research achievements specific to DARPA and of both military and private sector significance include rapid solidification superalloy technology for enhanced jet engine performance, artificial intelligence, packet switching, gallium arsenide integrated circuits, and the creation of the Materials Research Laboratories (now sponsored by NSF as the Interdisciplinary Laboratories Program).

IV. DARPA's Organization and Mode of Operation

Within DoD and, in fact, across the Federal Government's R&D activity, DARPA has several unique attributes. Critical to fulfillment of its mission to pursue high-risk, high-payoff research concepts and new scientific or technical developments of possible military significance is its organization and mode of operation. The Agency has no laboratories or other operations which become deeply involved in advanced development of research concepts of proven (or still seeking) technical feasibility. Hence, maximum flexibility is maintained to pursue radical new approaches to perceived problems/opportunities. Furthermore, DARPA pursues a policy of technological change. Research concepts or projects usually are explored for about three to six years to verify or disprove their viability. Those judged to be infeasible obviously are terminated. Those judged successful are transferred out through: (a) joint Service efforts; (b) pervasive incorporation in Services and/or private sector development efforts (this is particularly true of successful basic or applied research efforts); or (c) by self-imposed termination even if judged by DARPA to be successful. The point is that no scientific or technical concept, successful or not, is pursued indefinitely. This is crucial to the Agency's ability to have resources to respond quickly to unexpected opportunities. An additional aspect of this continual technological change is that, historically, DARPA has had a technical staff turnover with an average residency of several (4-6) years.

As a final note on DARPA's organization and mode of operation, and possible implications for the private sector, it is of interest to note some similarities in the organization of the often discussed Japanese MITI (Ministry of International Trade and Industry). MITI coordinates (and apparently highly successfully) national technical initiatives such as in Very Large-Scale Integrated Circuits (1976-1980). A current example is the "Next Generation Industries Program." Compare this program's goals--"R&D very useful to society and industry, but requires a considerable investment of both time (generally 10 years) and money, and is therefore too risky for private companies to conduct by themselves"--with the high-risk, high-payoff, technical feasibility goals of DARPA. This program, as with other MITI efforts, is of limited duration (ten years in this case) and is pursuing high-risk technological concepts in advanced materials, future electronic devices, and biochemical technology. Also, MITI has no laboratories, although it does create them for specific periods (e.g., five years) in support of specific projects. A current example is the Opto-electronics Laboratory which is developing a host of technical capabilities for communications and information processing.

V. DARPA Support of Research

DARPA R&D funds are comprised of research (6.1), exploratory development (6.2), and advanced development (6.3A) monies. Perhaps the best measure of DARPA support of basic and applied research in the sense of the Task Force definition is the Agency's investment in university research. This was $100.1M in FY 1984, or approximately 11.7% of DARPA's budget of $862M. In turn, about 15% or $15M of this university support was used to purchase instrumentation. A DARPA university funding history is attached as Appendix A. A survey of our university research efforts indicates that for every $100,000 to $200,000 of funding/per year, one PhD is granted (i.e., 500 or more in 1984). Also, 50% to at some universities as high as 75% of the PhD's granted in the engineering, computer, and physical sciences were supported in part at least by DoD.

VI. Selection of Projects and Specific Research Efforts

Assessment of ongoing research programs and evaluation of the potential of candidate new projects is done by the DARPA Director and his technical staff, under overall policy and objective guidance provided by the Secretary of Defense and the Undersecretary of Defense for Research and Engineering. The project evaluation/selection process makes extensive use of technical advice and determination of military relevancy by external groups such as the Defense Sciences Board, JASONS, USDRE's Advisory Group on Electron Devices, and DARPA's Materials Research Council. At the research level it is important to note that candidate projects frequently stem from small individual investigator grants of the Services' Research Offices as well as NSF. The synergism between DARPA's larger, focused, and generally more applied research efforts, and the individual investigator grants of its sister research agencies is a very effective process for innovation and subsequent proof of feasibility of advanced technological concepts. Industrial Independent Research and Development (IR&D) projects play a similar role in stimulating new projects.

Selection of specific research efforts in pursuit of an overall research project is done on a competitive basis wherever possible. In projects where possible approaches are very diffuse and difficult to define, well-publicized announcements such as Commerce Business Daily or Broad Area Research statements are used to encourage proposals with new concepts to address the project goals. When several technical approaches to a project goal can be reasonably well-defined, a more formal work statement is issued in a specific solicitation of proposals. In either case the technical expertise of the DoD (and other government) laboratory and research office staff is sought to evaluate and select those proposals with the most promise.

VII. Issues for Consideration by the Task Force

A number of issues should be considered by the Task Force in assessing the support of research by Government Agencies. I shall conclude with brief discussions of several issues of concern to DARPA.

a. Legislation Promoting Competitive Procurements.

In order to improve efficiency and competition in DoD's procurement of hardware, Congress has passed legislation which expanded substantially the procedures to assure competitive procurement. This legislation also is being applied to contracting for basic and applied research, and has further increased an already lengthy proposal-to-contract cycle. This makes it more difficult for DARPA (and other Agencies) to respond quickly to new opportunities, and discourages dynamic and innovative researchers from pursuing government research support. Clearly the purchase of or contracting for intellectual property (research concepts) is a matter quite different from that for manufactured radar systems or radar ranges. For example, publication of an intent to fund a research proposal to pursue a specific concept, so that others could bid if they have similar capabilities, can lead to the disclosure of proprietary information if an adequate concept description is published. Although the Competition in Contracting Act makes provision for the competitive selection of basic research through general solicitations, there is a need to extend use of this procedure. Perhaps extension to exploratory development (6.2 funds in DoD budgetary terms) contracts up to some size, say $500,000, would alleviate this problem.

b. Control of Unclassified Research.

The free-exchange of ideas and experimental results is essential to the success of basic and applied research effort, particularly within the academic community, and between it and the industrial and government R&E communities. On the other hand, it is well-documented that the Eastern Bloc seeks to capitalize on this free exchange to acquire militarily and industrially significant science and technology.

The balance between proper security and free exchange of scientific concepts is perhaps the most difficult problem faced by the Government and the research community today, and it is receiving widespread attention. Future policy must minimize any damaging effects of increasing communication difficulties within the nation (e.g., in university-industry technology transfer). Also, we must recognize that the leading research in a range of technologies is done in Europe, Japan, and other nations. We also must be careful not to stem the flow of innovative ideas into the country from overseas. This inward flow appears to take place through the academic community and a range of government-supported scientific activities (overseas fellowships, participation in and sponsorship of international conferences, etc.).

c. University-Industry Interactions in Research

This topic currently is enjoying a near euphoric expansion of activity. The challenge to Government science policy is to ensure that university/industry interactions remain at their current healthy state. At DARPA we strongly encourage contractual teaming of industrial and academic research capabilities in those many instances where the arrangement results in a unique research capability neither team member could ever expect to achieve alone. Our experience has been that geographic and communications

barriers to execution of these team research efforts rarely have caused any noticeable barrier to progress.

d. University Instrumentation

Recent assessments of university instrumentation have described the lack of state-of-the-art equipment in research universities. DoD has addressed this problem through the University Research Instrumentation Program (URIP). Nevertheless, the problem is of a magnitude that additional efforts are needed. Individual research grant programs cannot accommodate instrument purchases above $25,000 - $50,000 without devastating their "people support." The URIP has advanced this level to an average instrument individual award of $135,000. However, many individual pieces of today's state-of-the-art research equipment cost $500,000 to $3M, and require annually one-fourth to as much as one-half their initial cost for operation, maintenance, updating, and effective utilization. Basic research programs currently are not structured to encompass such individual initial expenditures and annual operating costs.

e. Foreign Nationals in Graduate Research

Widespread concern has been expressed about the high percentage of foreign nationals in the nation's graduate research programs. A survey in 1982 of DARPA-supported university research efforts suggested that about 30%-40% of the graduate students were foreign. However, nearly all (> 90%) have remained in this country (some with difficulty in obtaining work permits, etc.). The percentage of foreign nationals in these efforts appears to have decreased in the last year or two.

f. "Revolving Door" Legislation

Congress has been considering several versions of legislation designed to prevent DoD personnel from accepting employment at firms with which they have had contractual relations in their government position. Some proposed legislation would make it virtually impossible for such government employees to accept new positions outside the government--i.e., no or very few logical private sector employers would clearly be outside the "conflict of interest" sphere. At research agencies such as DARPA, such proposed legislation would make staff turnover difficult (most who leave go to the private sector), and hence stifle one aspect of creating technological changes in the Agency's programs.

I close with thank you again for the opportunity to present DARPA's views on its role in mission agency support of basic and applied research.

APPENDIX A

DARPA's University Funding History

Fiscal Year	($M) 6.1	6.2	Total
1974	21.9	12.6	34.5
1975	19.4	12.3	31.7
1976	17.1	10.5	27.6
197T	3.5	2.3	5.8
1977	17.2	9.2	26.4
1978	17.9	8.2	26.1
1979	21.0	9.7	30.7
1980	19.8	17.3	37.1
1981	27.3	13.8	41.1
1982	39.4	20.2	59.6
1983	46.4	30.0	76.4
1984	53.9	46.2	100.1
Final Grand Total	304.8	192.3	497.1

Mr. BROWN. That is fine, you did an excellent job.

Let me just discuss momentarily the management problem, Colonel Carter, I get the impression that you go to a rather extensive process to make sure that the work done by the labs under the jurisdiction of the various services is well coordinated and prioritized and responsive to what the management feels are the needs of the Defense Department. What about the situation involving interaction with other parts of the Federal laboratories system, for example, when you have some of these ebbs and flows in need for research both within DOD and within Energy or within NASA, how do you interact with these three laboratories outside of DOD in such a fashion that we may be able to optimize the total utilization of the laboratory system for the national interest?

Colonel CARTER. Well, Mr. Chairman, we do have an extensive cooperation and program formulation process that we use within the Department to put the programs together on basically an annual basis. It's really a system whereby we in the Department or in the OSD evaluate the requirements of the services and the operational commands, the unified and specified commands, and project the kinds of requirements that we think we will have downstream 15 to 20 years from now. Based on several inputs, as I say, from the operational, unified, and specified commands and also based on intelligence assessments of what we think the potential enemy may be doing, we provide that to the services in the form of defense guidance and say we think you guys need to do this kind of work for the next several years in your laboratories. The services then provide a technical program back to us within final constraints that says this is how we would like to address those problems that you have laid out. In addition to that, however, then that basically forms the basis for the budget request that comes to the Hill.

In addition to that, we do have a lot of coordination activities with the other departments. We have joint programs that we pursue technically with the DOE and with NASA. We have formalized meetings at the Under Secretary's level, my boss level, with NASA. We have a coordination exercise that is run under the auspices of OSTP under the Federal Coordinating Committee for Science, Engineering and Technology.

Insofar as the ebb and flow of mission agencies and the requirements for work within the mission agencies, it happens not only among this mission agency but within Defense too, and we use that as the opportunity, quite frankly, to adjust the amounts of resources that we are allocating to specific technical areas. As we assess our needs for the next 15 years or so, there are several technologies we think are very vital to us, materials and some of the technologies that Dr. Teich mentioned, some of them that we really need to get on with. As we increase the size of the defense budget in research and exploratory development, that delta increase will go into those particular areas, and by the same token as we are holding the other laboratories either level or decreasing their size a little bit, we accommodate that. We do basically the same kind of thing with the other agencies through similar coordination mechanisms. We looked at it several years ago, as a matter of fact, when

we were in the recession mode as an opportunity for the Department of Defense to pick up good engineers that were coming available from other agencies and we were fairly successful at recruiting engineers and scientists.

Mr. BROWN. Let me just ask one or two specifics, give one or two specific examples bearing on that.

When the Jet Propulsion Lab faced an obvious decline in need for their functions as far as NASA was concerned and sought other customers, looking at the Defense Department, would they deal directly with another Federal laboratory in the Defense Department or would they go to the level of the management of a particular service, like the Air Force, or would they seek some understandings at the level of the Department of Defense itself in trying to do that? How would that be?

Colonel CARTER. I think that happened in a couple of ways quite frankly. One was that the aeronautics people at the JPL became involved with the Army and at the lab level and also at the NASA headquarters level with our officers in the Pentagon to assist in moving some of—not moving the people—but moving some of the work to the JPL.

Dr. TEGNELIA. Mr. Brown, you may be aware of the fact that JPL is doing some work for the Army with regard to battle management systems. What happened in that particular instance, may be—

Mr. BROWN. Under the SDI?

Dr. TEGNELIA. No; in this particular case it's work for the Army.

Mr. BROWN. I see.

Dr. TEGNELIA. And what happened in that particular instance may be a good example of how that process works. The directors of the laboratory work with the Under Secretary and Assistant Secretary of the Army in order to be able to establish a framework for and agreement with the two organizations. There was a program manager's office that was established to be able to manage that activity. That program management office drew on not only the Jet Propulsion Lab people but also the laboratory people within the Department of Defense laboratories and they created a structure in order to be able to do a project. So it worked from the Under Secretary's office all the way down to the bench scientist to come to agreement on where there was room for mutual coordination, and that coordination has worked well over the last 3 or 4 years in this particular project.

Mr. BROWN. Is it codified in some sort of written agreement, say, between JPL and the DOD?

Dr. TEGNELIA. In this particular case, there is a program management charter which formalizes the particular working relationships and each individual or each party to the agreement understands fairly clearly what his responsibilities are in the process.

Dr. YOUNG. I would like to give two examples, one JPL, another known as NBS. Dr. DeLauer, who I think came in a minute ago, can probably shed much more light on this. I remember he and Dr. Goldberger had conversations, who is president of CalTech, had conversations at that time to move it along. So it was done at various levels, including the Under Secretary level and the president of CalTech.

At NBS, National Bureau of Standards, about three years ago, there was recognition both in DOD and NBS that DOD had measurement problems that can be helped by NBS and as a result of this Dr. DeLauer and Dr. Ambler, who is the director of NBS, came up with an agreement and there are currently two individuals, associates, assigned to my office from NBS who are roving ambassadors from NBS and go around and look at any measuring problems we might have and work out solutions for DOD. It works very well.

Mr. BROWN. Well, NBS has a history of doing this kind of work for other agencies and funding is transferred appropriately to take care of the costs of that sort of thing, and it seemed to be an efficient way to handle problems and manage resources also; and we are trying to determine whether the pattern there is applicable on a general, more general basis.

Let me ask for a couple more examples. We are getting into a policy supposition. Suppose we entered into an arms control agreement that limited further development of nuclear weapons, passed a nuclear test ban treaty or something like that. That would have a large impact on Livermore and Los Alamos, I presume. What would be our reaction? How would we handle that situation in terms of utilization of the laboratories? What mechanisms would exist for doing that?

Dr. TEGNELIA. Sir, you may be aware of the fact that the national laboratories have been working with the Department of Defense not only in the area of nuclear weapons packages but also in the area of conventional weapons activity. We do quite a bit of work with Sandia, for instance, in creating new conventional shape charges. Sandia and Lawrence Livermore have very interesting, let me call it, computer processing for smart conventional weapon systems. We have put quite a bit of effort in with both Lawrence Livermore and with Sandia on next generation armor systems for combat vehicles, making use of very different materials than straight steel armors. So there is quite a bit of precedent for trying to bring the national laboratories into the Department of Defense development process for conventional warfare, and I think that on the whole that process is one that is growing as the technology proceeds and I would expect the scenario of the type that you outlined would undoubtedly accelerate that process.

Mr. BROWN. We are talking here about Department of Energy laboratories which, of course, do a good deal and you are suggesting that there could be modifications in the work load for these laboratories that would move from an area which was no longer as much in need to one which had a higher priority.

Dr. TEGNELIA. Yes, sir. What I am trying to say is the technology that had residence in their organization has applications to conventional battlefield as well as to the nuclear battlefield.

Colonel CARTER. I think you are also aware that they are very extensive players in the Strategic Defense Initiative.

Mr. BROWN. Yes, I understand that.

Looking at the example that I gave, Dr. Tegnelia, of this higher velocity plane, this is a cooperative development also, as I understand it, DOD, NASA, and Commerce.

Dr. TEGNELIA. Yes, sir. We are still in the process of working out the management plan for that, but the intent is to involve those three organizations.

Mr. BROWN. There would be no question but what the management plan would require assignment of tasks to a number of different laboratories, I presume.

Dr. TEGNELIA. Yes, sir.

Mr. BROWN. And that would have to be coordinated at the departmental level, I presume.

Dr. TEGNELIA. Yes, sir. What we would imagine happening in this process is to have a fairly senior level, probably at the Under Secretary level, steering group which is responsible for making sure that the proper organizational talent is brought to bear on the program from each of the three organizations that you mentioned, and also to make sure that proper resources are made available to make sure the program can be fulfilled in a well-managed way. But we are in the process of doing that right now. We don't have all of the details of that worked out, and we will develop it this year.

Mr. BROWN. Mr. McKay, do you have any questions?

Mr. MACKAY. Thank you.

I am interested in knowing how responsibility in basic research is allocated between your two agencies, in laymen's terms. Would you say you are the one that is out more on the cutting edge of basic science?

Dr. TEGNELIA. Yes, sir.

Colonel CARTER. Perhaps some of the people in the services may disagree a tad because, indeed, in supporting jointly lots of programs between the services and DARPA, in addition the services programs are much larger than, collectively larger than the DARPA program. We try and select the best proposals that are submitted from the various performers, whether they be in academia, industry, or the in-house laboratories support.

Mr. BROWN. Now, in the National Science Foundation we spent a good bit of time asking questions about their peer review process—how we are making sure we are getting the best potential for the dollar we are spending? Do you have the equivalent of that in DARPA and in your agency?

Dr. TEGNELIA. Yes, sir. We try to do a peer review of almost all the programs that we have. Let me give you one example which has had quite a bit of history behind it. We have an activity called Materials Research Council, and that council has been in existence now for like 15 years, is currently headed by the director of Brookhaven National Laboratory, and they meet during the summer, plus periodically during the year. They are asked by us to give us advice on which areas of research show potential for major increase in the materials area, and we very oftentimes take the advice that they provide us on which directions that we should proceed. So that is an example of the type of peer review and peer advice process that we use. We do it in almost every major area.

Colonel CARTER. I would like to let Dr. Young address it.

Dr. YOUNG. In the basic research area we do use the peer review system in one form or another. There are slight variations from service to service. Some use outside agencies in the very formal strict sense and others use internal resources for peer review. In

the case of the Army, for example, it has a contract with the National Academy of Sciences to provide peer reviews on every single proposal that comes in. In the case of the Navy, they use more internal resources, using the Navy labs and their own ONR scientists and engineers to do review. In the case of the Air Force, both forms are used at the same time. The peer review system is used in one form or another every time.

Mr. MACKAY. Is it realistic to assume that there is coordination—I am interested primarily in the basic research area—that there is coordination between your efforts and those of NSF and NIH?

Colonel CARTER. Absolutely. We coordinate them not only between the services and our individual scientists work together from the offices of scientific research within these three services with not only DARPA but with the NSF. We have also about twice annual meetings with Dr. Bloch at NSF to talk about mutual problems and largely policy matters.

Dr. YOUNG. Coordination takes place at two levels, at the working level and the top management level. At the top management level as Colonel Carter mentioned, we have the NSF coordinating committee actually started by Bob Cooper at the time when he was director of DARPA and he and the director of NSF are the two co-chairmen, Eric Bloch and Colonel Carter. This meets about twice a year. There are many coordinating activities at the working level in each particular technology: materials, electronics and so on. There are quite frequent meetings, quarterly is quite typical, of DOD and NSF scientific offices to get together and exchange, formally sit down for a day, half a day, and exchange whatever has been happening at their agencies. Also proposals that are received are exchanged within a given discipline between DOD and NSF. So it's active at both the working level and top level as well.

Mr. MACKAY. And your priorities, as I understand your written testimony, are basically to assure that there is research that is being done that would keep us competitive in a national security and military sense.

Dr. TEGNELIA. If I might give you an example of the coordinating process that you were talking about, I mentioned the fact we are working very heavily in trying to continue the U.S. lead in computer sciences and information technology. We just completed a major review of Government work in the computer sciences area in order to make sure that we have had proper coordination, proper consultation and minimum duplication; and the report for that activity was sponsored by Dr. Keyworth's office. It has finally just become available now.

But what I wanted is to specifically spend just a few minutes telling you the people, the organizations that play, to give you the extent of the coordination that occurs. My organization participated, Department of Energy, Department of Commerce, National Science Foundation, NASA, CIA, NSA, and it was chaired by OSTP. So we work at the organizational level on specific topics to make sure that the coordination process, particularly on important national areas, is, in fact, fairly well done.

Mr. MACKAY. Thank you.

Mr. BROWN. Just to followup on that question briefly, and I don't want to belabor it, obviously DOD-supported research has kept the United States in the forefront of international commercial activities in a number of important areas: aircraft, computers—you could probably name several more. And, of course, you get criticized in the Department for diverting funds that might otherwise go to development of civilian technologies—unfairly criticized in many cases. But is there any place in the Department where thought is given, not only to the specific defense impact—of course—in computers and aviation, we are talking about dual use kinds of things—but to the overall question of maintaining our economic superiority as part of our, you might say, defense posture or predominance in world economic activities?

Colonel CARTER. Yes, sir. Recognize that most of the work that we do, the balance of it is indeed being done by universities and industry, and I had one company, fairly major company in the States, come through about 2 months ago and visit with me a while. As a matter of fact, they were interested—they had gotten out of doing business with the Defense Department back 15 years ago, and they were interested in getting back in, perhaps getting some support for some of their research from DOD. Their concern is that the technology that they developed in working under a DOD contract, would they be able to use and exploit that technology in the commercial sector and, gosh, the answer is certainly, absolutely. That is why we do it there, as a matter of fact.

To get back to one of the questions that perhaps was raised a little bit earlier regarding the industrial competitiveness, I think there is another player in this overall business of the economic competitiveness in various and sundry facets of our national economy such as the integrated circuit problem that we are currently having in California, such as the steel industry, automobile industry and so forth. That is, you know, the State universities can play a major role in interfacing with the research aspect of those particular companies who are experiencing those difficulties or who foresee those difficulties, and they did make a contribution to the economic vitality of that particular segment of our economy.

Mr. BROWN. Talking about automated manufacturing, I know the Defense Department has got a major interest in this, but it's an area in which we lag in the international competition, and I think it has a security implication. Frankly, this is at the thrust of, the heart of, of what I am trying to get at here.

Dr. YOUNG. Let me touch on manufacturing technology and manufacturing science.

Addressing manufacturing science in particular, we have two centers: one at Michigan and one at Stanford. That is run, I believe, by the Air Force. On manufacturing science, these are university centers. I am not sure how big the funding is. It is probably on the order of $1 million a year to do more or less basic research in manufacturing technologies such as automation, bringing together the sensors, the computers and all the pieces that come together under manufacturing technology.

On manufacturing technology as such, the Air Force Materials Lab has taken a lead in that and there again they are considering putting together an industry-Air Force board and starting a center

at a university, funding both by maybe 30 companies is what they would like to have and the Air Force. Maybe Jim knows more about that.

Colonel CARTER. DARPA does have major activities in this area.

Dr. TEGNELIA. There are several activities, one of which Dr. Young was referring to, particularly associated with the area of robotics and how one, in fact, tries to automate the manufacturing process. We are now in the process of developing through the organization that was mentioned, I think it's at Stanford, a series with the universities, a series of developments of vision systems, of robotic arms, of movers, which would help create a series of a new generation of robot, quote unquote. And the management model which is used there is to create a science center which brings together people who are working on that problem in a university setting because on some of this, for instance, vision systems and manipulators and the like, some very interesting work is being done at universities.

Ohio State, for example, does a lot of work for us in manipulators and levers. To bring the university communities together and the industrial communities together in the same organization, so the technology is transferred from the university base, some of the prototypes at the universities coming into the industrial center through this Stanford center and, therefore, transferred out to the manufacturing base to be used. It's clear while there are multiple applications for that, there are also significant civil applications for that, and we encourage the technology to have that general purpose application about it.

Mr. BROWN. Of course, our goal is to have all the dirty work in society done by robots and the next war fought by robots.

Colonel CARTER. Absolutely.

Mr. MACKAY. You obviously have worked with and I think have done a good job on coordinating the research leading to a specified aim, and that aim being to be competitive in a military sense. From our standpoint, as people who are trying to work with the policy implications of science and technology, would it not make sense for this country to try to orient its basic research in the nonmilitary side toward a recognition that we are also engaged in an industrial competition and would it not be sensible to start thinking in terms of research leading to industrial growth, industrial development? I understand that when you aggregate the statistics around that point of view that you can't find an awful lot that is going on in the American research establishment—in other words, research not aimed at robotics but maybe research aimed at places where there are going to be jobs in the future to give America a technological edge on the places where the jobs are. I saw statistics which may not be current that indicated in the order of three-tenths of 1 percent of our research was going toward industrial development and if you aggregated the Japanese and perhaps Western Europe research effort it would come out to maybe 15 to 20 percent of their research; and I realize there are some spinout and fallout from what you are doing, but, clearly, you are getting, remember, results by orienting your research toward specified goals and clearly you can make a case for what you are doing even

though in basic research some of it is speculative when you first start out.

Would it not make sense for us to orient our thinking around that kind of competition since clearly we are engaged in that competition as well as military competition?

Dr. TEGNELIA. I would like to give you another example that shows we, in fact, try to calculate that into what we are doing.

As you are probably aware of the fact, almost all of our integrated circuit technology is based on silicon as a basic material for doing that work. We have been interested in looking at another material, gallium arsenide, to do that work. It has certain military advantages. It's radiation hardened so you could work in the Van Allen Belt, for instance, but it also has both the military and commercial interests of being a faster processing material than silicon would be.

Now, we had worked that process in the laboratory for the better part of 10 years, and we came on the idea of an initiative, that it was time to get out of laboratories and into the producibility as spinningoff the problem we worked with. Right now I think there are three contractors who are working this in conjunction with General Abrahamson's Strategic Defense Initiative. There are three contractors who are sharing work with us to get that technology into production.

The way the division of effort was set up was the Government established the funding to produce chips and produce computers based on gallium arsenide if the company would invest in the facilities and in the production lines and the like to establish the capability for when the Government decided it had invested enough they would have a commercial capability already established.

As I mentioned to you, at least three companies are, in fact, sharing with us that way and, of course, they have chosen the positions for their facilities in a manner which would permit them to create jobs in an area where the expertise currently existed. So there was supplemental pay-back of job creation, new market generation and new product lines which were certainly of interest to the Department of Defense but also of interest, what we believe will be of interest to the commercial sector as well.

Colonel CARTER. I agree that it is a good opportunity to do that, and I think if one looks at some of the arrangements of the programs that are in the National Science Foundation, some of that sort of philosophy is coming through in the allocation of resources within NSF.

Mr. YOUNG. In discussions inside DOD we are very conscious of economic impact. Although it is not in our charter, we are aware of it. Much of what we support is dual use. It naturally has spinoffs. I don't want to belabor that point. DOD being in defense is motivated to produce a certain kind of product, weapon systems, but there are spinoffs, and let me be specific. We are very much aware of technology transfer in trying to do something about the Federal Laboratory Consortium.

One example was started by a DOD laboratory with the intention of transferring DOD technology into the civilian sector. Another example has not been mentioned, IR&D, so-called independent research and development, where we support part of it but the

companies decide what they are going to do and they bear in mind what strengthens their competitive position and yet DOD supports it because it's in our interest as well as in the Nation's interest. So we are doing this on many levels. Again, there is no concerted policy, but we believe we are contributing very much to the national competitiveness in the world.

Mr. MACKAY. Thank you.

Mr. BROWN. Thank you very much, gentlemen.

We have a number of other questions we would like to go into. You have just raised a number of them in discussing the technology transfer and laboratory consortium. We will ask you to expand in writing if we can impose on you.

[Answers to questions asked of Colonel Carter and Dr. Tegnelia follow:]

SCIENCE POLICY TASK FORCE

Hearings on Science in the Mission Agencies and Federal Laboratories

October 2, 1985

Followup Questions for Colonel Donald I. Carter

1. **How does DOD decide on the proportion of their to use for research?**

Specific, basic research goals are established each year via the Planning, Programming and Budgeting process. These amounts are modified by the prior year Congressional actions, DOD top line adjustments, inflation rate changes, etc., to arrive at the final budget submission in January of each year. We do not make a specific determination of the proportion of funding to use for basic research.

2. **How much DOD-sponsored research is performed at universities, Government laboratories, and industry and how is this research mix determined?**

Within the DOD research (6.1) program, the funding distribution for FY 1985 was approximately: universities - 50%, in-house laboratories - 30%, industry - 20%. The FY 1985 DOD research program totalled $861 million. This mix of performers is not determined by a rigid rule, rather by a continuing judgment by research managers. Factors entering into this judgment are the quality of proposals from potential performers, the scientific opportunity represented by the work, the availability of unique facilities or instrumentation and the demonstrated competence of the proposers.

3. **How are advisory groups used in DOD mission agencies in the formulation and execution of science policy?**

Advisory groups are an important element in DOD science policy formulation and execution. Within the Department of Defense, the Defense Science Board (DSB) and the DOD-University Forum provide the review, advice and perspective of the national science community. The Defense Science Board undertakes studies at the request of the Secretary of Defense, the Under Secretary of Defense for Research and Engineering or the Joint Chiefs of Staff. Reports are compiled by board members with expert outside assistance. These reports provide detailed findings and recommendations to the Department for consideration in determining its science policy. The DOD-University Forum, established as the result of a DSB recommendation and composed about equally of senior DOD personnel and university officials, has given advice on a wide range of research and education issues related to national defense. Within each Service there are advisory groups which operate along lines similar to the DSB. These groups provide recommendations on programs, policy and laboratory oversight. The Service advisory groups are: the Naval Research Advisory Committee, the Army Science Board, and the Air Force Scientific Advisory Board.

4. How does the DOD provide incentives for joint projects between universities, or between universities and industry?

A recent innovation in DOD's extramural research program has been the establishment of multidisciplinary "cluster" programs focused on complex DOD problem areas. These programs, which provide at least three years or more of stable support, are carried out by groups of researchers at universities. Each group is managed by a senior scientist, who serves essentially as program manager, providing clear direction and coordination. Examples of such programs are the tri-Service Joint Services Electronics Program (JSEP) and the Joint Services Optics Program (JSOP), in which the Army and Air Force participate cooperatively in supporting major projects. Although JSEP is not new, this concept of research management is now being emphasized more strongly. In 1976 only 25 programs were of this nature. Over 130 such programs exist today.

Industry-university collaboration is encouraged by incentives in the Independent Research and Development (IR&D) program. In the review and negotiation of corporate IR&D ceilings, credit is given to companies which have strong university interactions in their IR&D program. Additionally, university involvement with small businesses is encouraged by the Small Business Innovation Research (SBIR) program.

5. In your view, to what extent does defense-supported research yield technology which is applicable to the civilian sector, and vice versa?

Technology developed as a result of DOD research has found application in the civilian sector. In addition to improving our defense posture, DOD technology has increased our industrial competitiveness in today's high-technology world. Radar, synthetic rubber, integrated circuits, advanced optics, lasers, resuscitators and heart pumps head a lengthy list of DOD-sponsored technologies which have benefited the private sector. This process is a two-way street because civilian developed technologies are being exploited to solve problems of the armed forces. A current example is biotechnology where research is being performed by DOD to create new protective gear and treatment methods for naturally occurring infectious diseases, and chemical and biological agents.

6. Since the Department funds R&D mainly by contracts rather than by grants, are research and development contracts subject to the same requirements as major procurements contracts or are they adapted to research funding?

Policies and procedures of special application to research and development (R&D) contracting are given in Part 35 of the Federal Acquisition Regulation (FAR). For basic (6.1) research adaptations have been made: (a) special competitive procedures and (b) short form research contracts. Under FAR Section 6.101 basic research (6.1) awards are considered competitive when they result from (i) a broad agency announcement that is general in nature, identifying areas of research interest, including criteria for selecting proposals and soliciting a response from all capable offerors and (ii) are subject to peer or scientific review. This procedure is used by the Service research offices and is being implemented at some DOD laboratories. The short form research contract (DOD FAR Supplement

Subpart 35.70) is an allowable instrument for contracting with educational institutions and nonprofit organizations. It may be used to contract for research based on a proposal submitted in response to a broad agency announcement. It provides for standardized proposal format, incorporation of uniform contract clauses, and inclusion of the original or modified proposal as part of the contract. These serve to lessen the administrative burden on universities in the contracting process.

7. **How are 6.1 and 6.2 funds distributed among performers?**

The estimated FY 1985 percentage of the 6.1 and 6.2 programs accomplished by in-house laboratories, industry, colleges and universities is shown in the following table:

Percent of 6.1 and 6.2 Program by Performer

Performer	Program	
	6.1	6.2
In-house laboratories	30%	33%
Industry	20%	59%
Colleges and universities	50%	8%

8. **How does DOD determine its share of the total contribution to the science infrastructure? How are education and equipment and facilities coordinated among the various parts of DOD and among the various mission agencies?**

DOD recognizes that support for the science infrastructure is important in maintaining the strength of U.S. science and technology. The DOD supports this infrastructure to meet the defense research needs. The DOD has been increasing its support for advanced instrumentation and fellowship programs which will strengthen the infrastructure and enhance the ability of colleges and universities to conduct quality research and produce well-trained graduates. For example, the DOD University Research Instrumentation Program, started in FY 83, was designed to approximately meet the estimated DOD share of university research instrumentation needs.

Coordination of infrastructure (education, equipment and facilities) programs follows the methods used to coordinate the research program. Interagency coordination is achieved through the Federal Coordinating Council; for Research, Science, Engineering and Technology (FCCSET) and formal arrangements with NASA, DoE, and NSF. Within DOD, the Deputy Under Secretary of Defense for Research and Advanced Technology, through the Director for Research and laboratory Management, provides oversight and coordination for these programs.

9. **How does the DOD control publication of 6.1 research results and 6.2 research results? How much basic and applied research are classified?**

The DOD policy on the publication of the results of sponsored research follows the National Policy for the Transfer of Scientific, Technical and Engineering Information published on September 21, 1985. That states in part: "It is the policy of this Administration that, to the maximum extent possible, the products of fundamental research remain unrestricted. It is also the policy of this administration that, where the national security

requires control, the mechanism for control of information generated during federally-funded fundamental research in science, technology and engineering at colleges, universities and laboratories is classification."

Determination of the classification level appropriate for a project is made prior to the award of a research contract. Controls on the publication of unclassified research results, if required, will be agreed on and will be so stated in the contract.

A survey of project sheets covering DOD sponsored research and development between 1978 and 1983 showed:

- About 0.6% of the Research (6.1) was classified and most (71%) of that was DOD in-house laboratory research with the balance conducted by industry.

- About 2.1% of the Exploratory Development (6.2) was classified. Of that amount, in-house laboratories conducted 61% and industry 28% followed by universities and non-profit organizations at 7% and 4%, respectively. University classified research was conducted at university-affiliated "Research Institutes".

10. **How much of the DOD technology base funding is directly weapons-related and how much is more generic in nature, that is, of interest to the civilian sector as well as the military sector?**

The DOD technology base consists of basic research (6.1) and exploratory development (6.2). The basic research program is predominantly generic in nature but is focused on those technologies and disciplines which are of interest to the DOD. The exploratory development program is more applied and addresses such topics as avionics, chemical defense, advanced weapons, submarines, high energy lasers, etc. Thus the technology developed is of prime interest to the military and is weapons related. However, a large number of the principles and techniques developed under the technology base program can have application to the civilian sector. Most of the work in the technology base is unclassified and results in reports which are given unlimited distribution to encourage technology transfer.

SCIENCE POLICY TASK FORCE

Hearings on Science in the Mission Agencies and Federal Laboratories

October 2, 1985

Followup Questions for Dr. James A. Tegnelia

1. **Your data for DARPA university funding history shown in Appendix A of page 6 of your prepared testimony indicate a significant increase over the past five years. Is this upward trend expected to continue, or have you reached a spending plateau? Do you anticipate a future decline?**

The increase in university funding since FY 1976 - FY 1978 has come about through several factors. First, DARPA has been largely responsible for initiation and funding of research in the computer science activities such as artificial intelligence and systems architecture. These efforts were approaching a steady level in the early 1980's, but have received recent (FY83-FY85) enhancement due to the initiation of the Strategic Computing Program, in which university research has an important role. Since this new program attains full funding level in FY 1986, further significant increases (beyond inflation) in this area are unlikely.

Second, in the period FY 1972-FY 1975 DARPA transferred its pioneering Interdisciplinary Laboratory (IDL) Research Program to NSF (the NSF Program now is called the Materials Research Laboratories--MRL's). DARPA's IDL support went from $17M in FY 1972 to zero in FY 1976. since that time, new individual initiatives in Defense Research Sciences (particularly for materials, microelectronics, biological materials, and more recently electro-optics) have been initiated and now are stabilizing at an annual funding of about $13M - $16M annually.

In the long term (next five to seven fiscal years), DARPA anticipates that existing research projects in these two areas (computer science and defense research sciences) will decrease as projects are completed, and the Agency turns its attention to new technological opportunities. However, fulfilling the Agency's mission always will require support by a strong university research program, the content of which changes over five to ten year periods to match demands of new technical thrusts. Consequently, we anticipate that these existing programs will be replaced by new research thrusts in areas such as those now "seeded" but currently not receiving major emphasis, e.g., fluid dynamics/turbulent flow, exploitation of unique properties of biological materials, nanometer size structures, application of expert systems to materials growth and processing, and exploitation of inexpensive multiprocessor supercomputational capability in modelling and understanding physical phenomena.

2. **You state that research programs are evaluated on the basis of technical advice and determination of military relevance. How do you determine military relevance for basic research programs?**

DARPA's mission is to explore and evaluate radical technical concepts, usually at a function or system level, which may produce dramatic new military capabilities if they could be reduced to practice, and also to minimize the chances of analogous technological surprise by any potential adversary. To answer adequately speculative technological "What if...?" questions which arise in fulfilling this mission, basic scientific insight must be acquired related to such topics as realizable materials properties, future size-volume-weight-power requirements to achieve a certain level of computational capability, etc. DARPA's university research efforts are evaluated and selected to provide the missing scientific data required to answer these "What if...?" questions. Hence, these efforts directly support the Agency's assigned mission and are relevant to evaluating potential future directions of militarily significant technology.

3. **How many new projects versus continuations of projects are undertaken by DARPA each year? How do new projects get funding?**

The percent of new projects in any given year average between ten and twenty percent. The origin of defense future technology thrusts is the DOD Defense Guidance Manual issued annually by the Secretary of Defense. DARPA participates in the formulation of this guidance and responding to its direction. Participation and response evolve from DARPA's direct involvement in broad innovative research fields and general awareness of future DOD needs. New projects to support this direction result from DARPA announcements of fields of interest and from unsolicited research proposals from private industry, universitites and Government laboratories. Funds are planned in selected research fields and submitted in the DARPA budget request to Congress.

4. **To what extent does defense-supported research yield technology which is applicable to the civilian sector and vice versa?**

Defense supported research and civilian sector supported research co-exist in a truly symbiotic relationship in which each yields technology significant to the other sector. Perhaps of greatest significance in today's information, communication, and data processing environment is the invention and subsequent development of the integrated circuit (IC). The heart of the IC, the transistor, was invented at Bell Laboratories in 1947. In the period 1950-1960 DOD funded an extensive research thrust seeking a low power, reliable "molecular electronics" to replace vacuum tube circuits in military systems. This research thrust created an atmosphere which catalyzed the civilian invention of the IC (at Texas Instruments and Fairchild Semiconductor) in 1959. Subsequent development of the IC concept in the period 1960-1967 was greatly enhanced by DOD research funding whose particular goal was airborne solid state phased array radar based on IC's and not possible with vacuum tube technology. Since 1967, the commercial market for IC's has spurred extensive civilian research to advance IC

design, processing methods, and processing equipment. DoD now exploits these advance to develop IC's for its own special needs. Finally, the decade of the 1980's has seen the pressure to realize near-term profits cause the semiconductor industry to focus its resources on near-term (one to three years to production) development efforts. Much of the basic research in semiconductor materials, processes, devices, and IC design is being done at universities under DoD as well as other Federal Agency support. This support has become particularly important since the court ordered breakup of AT&T and its impact on Bell Laboratories has reduced the flow of basic research results from that organization into the civilian sector.

Tabulations of representative research contributions of DOD and the Civilian Sector and their impact on each other follows.

DoD Research	Civilian Impact
Gallium Arsenide Devices (1960's)	Light emitting diodes
Gallium Arsenide IC's (1970's-80's)	Satellite communications High performance computers
Superalloys (1950's-70)	Commercial aircraft engines
Rapidly Solidified Alloys (1975-85)	Improved aircraft engines Automotive components
Night Vision/Infrared Imaging Equipment	Security, safety systems
Conducting Polymers	High power density batteries
Computer Aids for IC Process Design and Specification	Production of IC's
Computer Netting	Timesharing, computer communications networks
Selective High Sensitivity	Implanted microsensors for realtime medical monitoring

Civilian Research	DOD Impact
IC Fabrication Processes and Equipment	Reliable radiation-hard IC's for military electronic systems
Biotechnology	Sensors for chemical and biological defense unique materials for enhancing DOD systems performance
Polymers, Polymer Chemistry, and Polymer Prescursors	Composite materials, bullet proof vests, clothing. Raw materials for high temperature ceramics and semi-conductor fabrication
Superlattice and Heterojunction Semiconductor Concepts	High performance devices and circuits for radar, ECM, EW, computer, and communications systems
Optical Fibers	High data-rate, interference free communications

Mr. BROWN. Our last witness has been very patient, Dr. Richard D. DeLauer, former Under Secretary of Defense for Research and Engineering, and we very much appreciate your allowing us to impose on you, Dr. DeLauer, and we will get you through here promptly.

[A biographical sketch of Dr. DeLauer follows:]

DR. RICHARD D. DELAUER

The Honorable Dr. Richard DeLauer is president of the Orion Group Ltd., incorporated in the State of Virginia on December 1, 1984. The Orion Group Ltd. performs professional services for multiple clients to include analysis of technical proposals, market and technical forecasts, financing planning, evaluation of commercial opportunities for product development and product application for both defense related and non-defense related markets. He also serves as a consultant to the Office of the Secretary of Defense.

Prior to forming The Orion Group Ltd., Dr. DeLauer was appointed by President Ronald Reagan to serve in the United States Department of Defense as the Under Secretary of Defense for Research and Engineering (USDRE). Dr. DeLauer was confirmed by the United States Senate as USDRE on May 6, 1981 and served until his resignation on November 30, 1984.

As the USDRE, Dr. DeLauer was the principal advisor and assistant to the Secretary of Defense for Department of Defense on scientific and technical matters; basic and applied research; development and acquisition of weapons systems; communications, command and control; atomic energy; and intelligence resources. He also served as the focal point for all test and evaluation matters, and was the Defense Acquisition Executive (DAE).

Prior to his appointment as the Under Secretary of Defense for Research and Engineering, Dr. DeLauer was responsible for TRW Inc.'s Systems and Energy activities, which employed more than 20,000 people, and provided a wide variety of products and services for aerospace, electronic, industrial, civil and commercial markets.

Dr. DeLauer joined TRW in 1958 following a 15 year career as a naval aeronautical engineering officer. In 1960 he was made director of the Titan ICBM program. Dr. DeLauer was named vice president and general manager of the Systems Engineering and Integration Division in 1965, and assumed the position of vice president and general manager of TRW Systems Group in 1968. He was elected an executive vice president of TRW Inc. in 1970, and to the Board of Directors in 1972.

He is a member of the National Academy of Engineering and a fellow of both the American Institute of Aeronautics and Astronautics and the American Astronautical Society.

Dr. DeLauer is the co-author of two books, *Nuclear Rocket Propulsion*, and *Fundamentals of Nuclear Flight*, and has served as visiting lecturer at UCLA on nuclear rocketry.

Dr. DeLauer graduated from Stanford University in 1940 with an A.B. in mechanical engineering. He received a B.S. in Aeronautical Engineering in 1949 from the U.S. Naval Postgraduate School, and an aeronautical engineering degree (A.E.) and Ph.D. in Aeronautics and Mathematics from California Institute of Technology in 1950 and 1953.

Dr. DeLauer was born in Oakland, California on September 23, 1918. He and his wife, the former Ann Carmichael, have one son, a granddaughter and a grandson.

STATEMENT OF DR. RICHARD D. DeLAUER, FORMER UNDER SECRETARY OF DEFENSE FOR RESEARCH AND ENGINEERING, AND PRESIDENT, THE ORION GROUP LTD, ARLINGTON, VA

Dr. DELAUER. Thank you, Mr. Chairman.

I will give you some time. I have a short statement which I am going to submit for the record. I don't intend to go into detail. My posture statement from 4 years of submitting that to Congress pretty much summarizes how the Department functions in the basic research.

I thought I would at this time kind of focus on some of the things I was sitting in the back of the room listening to.

This whole question of coordination, I know you were very much interested in. It's a reasonably formalized activity; it's not ad hoc. I was a cochairman along with Hans Mark when in the coordinating committee we covered in detail, generally on a 6-week basis, all the efforts going on so that at least we identified areas that looked like duplication and attempts to be as efficient as possible.

There is also another matter which was very, very important that not much was said about. I was chairman of what is called the Intelligence Research Development Council which has every single research director in the Government that has anything to do with research, that has to do with the intelligence field, and we met on a 6-week basis and we had complete carte blanche from the director of Central Intelligence to be able to look at all the intelligence programs and make firm recommendations to him on programs that we had to do. That permitted, in certain cases, activities being covered by the agencies, for instance, to be funded, to be identified for it to be able to be taken advantage of. That was a very powerful committee and very, very well done and money that we spent in that research and development area was done very well.

These meetings covered the whole spectrum of what we could do at Caltech. I had a personal interest being a Caltech graduate. I wanted to see the alma mater succeed, and so he and I worked on the problem, and then I sat down with the assistant secretaries of the services and said, "Look, what programs can we fit in there?" We were successful in JPL. Then the Army started a program that got the faculty all upset. They had had to change the rules there, but we do that.

Mr. BROWN. You couldn't do anything to get the planetary exploration budget increased.

Dr. DELAUER. That is right. We couldn't quite do that. But we sure gave it a go.

On the question of: Is the Department of Defense research program so focused that the question of the utilization and general economy is really happenstance, more than you would expect and you would hope? There has been a tendency to have that as the case, particularly in the research being done by the companies.

Leo mentioned just briefly, and almost in passing, an activity called independent research and development. That is a large amount of money. It runs anywhere from ½ to 2 percent of the total DOD procurement budget, and they have very strict contracting. I used to have to go before Mr. Adabbo every year. We counted the nickels and pennies and he wanted to be sure we were spending the money.

But going back in history, remember there is a proviso by statute which is called the Mansfield provision, which is handcuffing the companies from being able to in many cases get in the basic research area. When they have to show military relevance, in many cases they will not undertake that type of basic research because they will get it disapproved.

I think this committee ought to really look at this thing since you are the only committee that really looks at the whole question of science and technology in the country; all the rest of them are parochial. The energy committee looks on the energy side. We in Defense, in the oversight by Congress in the defense area, look at

theirs. Senator Proxmire gives Golden Fleece Awards a" the time, and so everybody is worried about that. But this commi ee—I have talked to the chairman of the full committee—this committee has got the opportunity, and now you are having the hearings, to look at this thing from a broader standpoint than just the mission-oriented sort of things. I think most of the departments have really become accustomed to being mission-oriented. In my statement, you know, in the very first paragraph I tell you that our research is driven by military needs, which is absolutely true. But the thing is, is the independent research and development which is carried on by the industry and along with universities is a matter where we have an initiative. I gave the contractors kind of brownie points. They got a little higher grade, they got more reimbursed if they would bring universities in to assist them in the independent research and development. As a matter of fact, when I was at TRW, at UCLA we developed a whole new generation of isotope separation on research, and that was all done at UCLA. The brains were there. What we provided were the laboratories and money, and they went ahead and did that.

I would hope that this group would, indeed, take a look at IR&D and the Mansfield amendment. It's beyond the point where it is. There is no way to separate basic from military needs and civilian needs. At the basic level you never know where you are going to go. Nobody knows that microbiology may end up being an electronic device. It looks like that is where we are going to go pretty soon.

Mr. BROWN. Molecular computers.

Dr. DELAUER. Yes, sir, and the whole question—let's take chemistry. We should be looking at the chemical industry, but the chemical industry is treating mental disorders now. You never know where it is going to go. To put it in a straightjacket I think is an error, and you in the congressional role of oversight ought to go back and take a look at that. I think it would be something that would be well worthwhile.

If I could do anything for this hearing, contribute anything, it is to make you gentlemen just re-examine it, debate it, see whether it's worthwhile, because that is a little bit of a handcuff, and we can't afford that now. Your statistics are absolutely correct. In the case of Western Europe, everything I had to do as armament director, when I went over there to push on them to try to use some of the emerging technology to give them better security, security was important, but jobs were No. 1. Jobs are first, and security is second in Western Europe. We are their security and so we have got to make more out of our research dollar, and one of the ways is to unfetter it a bit. You are still going to have the review process. You are still going to have to fit it in the particular budgets. So there are constraints other than military relevance. That gives you enough.

[The prepared statement of Dr. DeLauer follows:]

U.S. HOUSE OF REPRESENTATIVES

COMMITTEE ON SCIENCE AND TECHNOLOGY

Statement by R. D. DeLauer for
the Task Force on Science Policy

Mr. Chairman, thank you for inviting me to present some of my views on the government/science relationship, and the direction which this relationship should take in the future. I would hope that by carrying out this task, you will develop recommendations that will help the Congress understand the high leverage which mission-oriented basic and applied research can provide to both our national security and domestic economic growth.

During that period that I served as Under Secretary of Defense for Research and Engineering, my annual RDTE posture statement to Congress gave a comprehensive picture of the role of the Service laboratories in carrying out basic and applied research, so I will not repeat those views here. Instead, I would like to present my perspective on the role of basic and applied research in support of national security, and I will try to show how this effort can be transferred to the non-defense arena with positive results.

In general, the military threat "drives" the need for the Defense Department to sponsor both basic and applied research. To give a specific example, let me quickly review the history of the successful Very High Speed Integrated Circuit (VHSIC) program. In the mid-seventies the evolving Soviet threat in submarine and electronic warfare, and their initiatives in increased mobility led the Department of Defense to realize that a significant increase in research and development of high speed signal processing had to be undertaken. It was also clear that their current microelectronics would not be adequate to do the job. Up to that time, microelectronic basic and applied research programs had been paced by commercial needs, primarily those of the computer industry. During that period, computer requirements did not include very high speed circuits. Accordingly, Bill Perry, my predecessor as the Under Secretary of Defense for Research and Engineering, initiated a program whose objective was to develop a family of microelectronics chips that would result in orders of magnitude improvements to Anti-Submarine Sonar, synthetic apeture radar and secure voice equipment. The VHSIC program has been in existance for almost a decade, and has been an outstanding success. Without DoD initiative, the need for these chips would not have developed - the commercial market still does not have a requirement for processing equipment with VHSIC capabilities.

The unique feature of the VHSIC program was the concept of an industrial/university team, and making the resultant technology available to the civil computer industry, as well as the military. This concept is currently being employed in the Defense Research Project Agency's (DARPA) strategic computing program.

In closing these brief remarks, let me give you some examples of research programs initiated by the Department of Defense that proved to be beneficial to the non-defense sector. They have included:

Time Share - Developed by DARPA in the early 60's Time Share became a significant commercial success in the mid-70's.

Packet Switching - Developed by DARPA in the late 60's, now just being introduced by commercial telecommunicators.

Fifth Generation Computer - Results of DARPA sponsored research at Stanford, MIT and Carnegie-Mellon. Appropriated by Japan for world-wide exportation.

As disclaimed in my introduction, this statement was not intended to be definitive or all inclusive, it was intended to give the task force some feel that mission oriented departments like the Department of Defense need to sponsor basic and applied research when the military needs dictate and that these programs have had a positive benefit to the non-defense sector.

DISCUSSION

Mr. BROWN. Thank you very much, Dr. DeLauer.

That is precisely the sort of thing we want to look at. The function of this group is really to look broadly at the policy issues with regard to all of science and technology. I think this specific suggestion you made with regard to the Mansfield amendment and independent research are excellent examples of that.

Along the same lines, I have heard frequently with regard to the Federal laboratories if we do do a better job of utilizing the creative energy of laboratories, if we provide more leeway to the laboratory directors in terms of the expenditure of their budget, perhaps give them a little independent research of a reasonable amount, I don't know what it would be, maybe 1 or 2 or 5 percent or something like that, but it would allow them to focus on targets of opportunity more than they have been able to at the present time. Would you concur in that?

Dr. DELAUER. I think that is a device, one of the devices for it. You will find the complaints out of, at least let me talk about DOD plans, which I know quite a bit about, and we tried some different management approaches, for instance, with the naval labs. We said, "Look, we are going to let you have a level of funding, and you can use that level of funding kind of in an industrial way. In other words, you pick the projects you do and if you want to hire some bright young guys to do that, you go ahead. We are not going to put a manpower ceiling on you and we are not going to hold you to certain kind of rules and in regard to your internal managements." And it has proved very effective as far as the Navy. They went to try to do the same thing in the Air Force and ran into a completely different culture, because generally the services are the opposite that way.

In this case there was a difference, there was a detailed report written by a task force that we had put together at about 1982 on the management of the labs and their people and what it looked like, and they covered both of those subjects. I think it would be good as background information for your hearings. But a certain amount of initiative at the source of the research is absolutely essential if you are going to get the best people to do the best thing, and so I would urge you to take a look at that and if you think that there is too much constraint because of when you put it to OMB and the Office of Personnel Management, congressional committees, pretty soon you find they have constrained the opportunity for research.

We are good. We have got great research. I am telling you all you have to know is how the Soviets are targeting our research. You know that we have got great research. You know that our problem is in something you ought to look at which is the education of the United States in the higher degrees and is something that ought to be done. I had a specific suggestion when I was in the department, never got far, which was to broaden programs like ROTC, for instance, to where you could you would include and pay for the education of bright youngsters who would not necessarily put the uniform on but would give national service, either come into a laboratory for 4-or 5-year terms or stay assistant professors

where we are short of, as an obligation to pay off their college degree, much better than lending them the money and they don't pay it back anyway, if you could recreate an ability to have a broader thing than just the students that end up putting on the uniform.

Mr. BROWN. Would you make that in concrete form, Dr. DeLauer, so that we can look at it.

Dr. DELAUER. Sure.

Mr. BROWN. That is a problem that runs——

Dr. DELAUER. It can be Senate service, any place. It wouldn't have to be DOD, National Science; teaching is one of the things I think at the assistant professor level is probably our deepest shortage. Because of being U.S. nationals and passing security clearances, the industry has snapped them up and as a consequence 50 percent of more of the Ph.D. candidates at major universities are foreign nationals. We are educating the competition. We really are.

Mr. BROWN. We hope it is just the friendly competition.

Dr. DELAUER. Well, it is. It is never not friendly in the marketplace. It may be a friendly net, that is, but a lot of them are going to Toyota.

Mr. MACKAY. I think that is a very important point, and a variation on that same theme is the whole question of university instrumentation and capital outlay needs. We are sort of backing into a situation where we are creating an international competition and given in our Federal system historically we have left the responsibility for the raising of the money and the education of the young people at the State level and they clearly are not able to carry that responsibility.

Do you see—I know DOD is trying to help with the instrumentation problem, and I think they are to be applauded for that—do you see a policy need for the Congress to really rethink the questions on the responsibility for instrumentation?

Dr. DELAUER. Absolutely.

Mr. MACKAY. That is going to end up being the Achilles' heel in the whole operation.

Dr. DELAUER. I will give you a concrete example. I was in fundraising for Stanford as a undergraduate and during the period I was talking to the people in the medical school and they had a biochemist they wanted to hire from the University of Chicago. He came with a $500,000 price tag for instrumentation for his laboratory. Good professors are more expensive than hot shot football players to recruit and if they will come to your school it is important. That is the marketplace, and the University of Texas is doing a terrific job of using their resources to create a center of excellence. In the past they haven't had, and the price of centers of excellence are going up almost exponentially. It is not linear. And so anything that the Federal Government does in doing their mission, I don't think you ought to create anything so artificial that it becomes a political issue in the mission. If you could urge the people doing their mission to be sure that these are the kind of check list we need to have—better instrumentation programs, the whole question of better education base, opportunities for people to serve and yet not have to put on the uniform—things like that, it would contribute to the scientific substance of our country.

Mr. MACKAY. I was even thinking in terms of if you assumed that the raw material of the next generation of industrial competition is the human mind, then you could say from that that we ought to rethink what we are doing in public works. I mean Congress should, in effect, have a policy that had the Federal Government assuming responsibility for capital needs in higher education.

Dr. DELAUER. We have got good examples of works. I can remember early on in the space program, when Senator Kerr was the driving force in the Senate, and when President Johnson, I guess was president, why, I was at TRW then. The response was: "You guys on the West Coast captured the aircraft business because of your universities and your research centers. You are not going to capture the space business. We are going to make the Southern Crescent something else."

Mr. BROWN. Don't you think we have overdone it by putting all those space facilities in Texas and Florida?

Dr. DELAUER. I am a Californian, so are you. I tried to get it in San Bernadino when you and I were out there together. We never quite made it.

Mr. BROWN. Dr. DeLauer, we appreciate your being here. We know you have an urgent appointment, and we want to thank you again for taking the time.

Dr. DELAUER. Mr. Chairman, as you know, this is a favorite subject of mine.

Mr. BROWN. I know it is.

Dr. DELAUER. Anything you can do to help, I appreciate it. I wish you had more time and I had more time. Thank you for the invitation.

[Whereupon, at 12 noon, the Science Policy Task Force adjourned, to reconvene on Friday, October 4, at 9:30 a.m.]

[Answers to questions asked of Dr. DeLauer follow:]

ANSWERS TO QUESTIONS FOR THE RECORD

Dr. Richard DeLauer

1. Is it possible to determine an optimum balance between civilian and military support for scientific research? How might this best be determined?

ANSWER

I do not believe it is possible to determine an optimum balance between civilian and military research. One of the problems is the lack of a credible data base on just how much is being spent at any given time in each area of research. Another problem has to do with the definition of civilian and military research. Since in general civilian research is driven by market forces, while military is driven by the requirement to meet a changing threat, it would be better to try to examine the issue on the basis of industrial and/or academic research.

2. How can DOD make the best use of diverse research performers such as universities, in-house laboratories, industry and not-for-profit organizations?

ANSWER

Since DOD does a reasonable job of utilizing all of the above institutions, it should focus on improving the "process". Since most of industry initiates their research as part of their IR&D programs (which has reasonable oversight performed by DOD) while USDRE I instituted a program that encouraged defense related industries to involve universities in the companies IR&D activities. This program has been marginally successful. Another means of utilizing these institutions is to ensure that university research (6.1 and 6.2) be for the most part unclassified. This is now the case. After a fierce internal battle in DOD, and with the support of the White House Science Advisor, the President did sign such a directive a couple of months ago.

3. What is DOD's current policy on the classification of 6.1 and 6.2 research? How is this policy being implemented, and what impact does it have on the research performers, particularly at universities?

ANSWER

By classification I am assuming you mean security classification. 6.1 and 6.2 have elements that are both classified (up to the highest levels), as well as unclassified. The issue with universities has been over the question of when research becomes classified, and the requirement for prior review before publication. With the promulgation of the Presidential

directive mentioned in the answer to question 2, these issues have been diffused to a great extent. University research funded in the 6.1 and 6.2 categories will be determined to be either unclassified or given a classification prior to funding. If unclassified, there are no restrictions placed on the university, on who can work on it, or what can be published. If an area is classified, the university has the choice of accepting the funding and complying with the rules, or refusing to do the work. A free choice in effect. Reactions from many of the universities that, by policy, will not accept classified projects seems to be that this new policy is workable. I would like to point out that many universities will, and are eager to conduct classified research.

4. In your testimony, you stated that the Mansfield Amendment "fettered" DOD's support of basic research, and hindered DOD's ability to allocate its research funding for a greater impact on the national objective of increasing international competitiveness. Could you please expand on the impacts of the Mansfield Amendment, and DOD's contribution to industrial competitiveness?

ANSWER

The Mansfield Amendment requires that any DOD funded research, either as reimbursed IR&D or contracted effort, must be shown to have a "military relevance" prior to approval of the research effort. This is nonsense. At the 6.1 and 6.2 level it is in most instances impossible to make a distinction. In the large, all effort has some relevance to national security, (i.e., economic strength). Taken in the small, who can, with any confidence, be explicit in what the specific applications of the research might result in, or, which application will be militarily relevant? The Mansfield restriction is just a club in the hands of the many "nay sayers" that are against DOD sponsored research.

The list of DOD sponsored research to industrial competitiveness is extensive, so let me give you a few examples. Most of these efforts were originally sponsored by DARPA.

Computer Technology
Time-sharing
Fifth Generation Computers (appropriated by Japanese)
Pocket Switching
VHSIC
Jet Engine Development

5. During your testimony, you suggested a form of national service to fund the graduate education of scientists and engineers who would then be obligated to teach at a college or university, or perform research at a federal laboratory for a certain period of time. Could you please expand on this innovative solution to shortages of scientists

and engineers?

ANSWER

Since for the foreseeable future, the DOD is dependent on an all volunteer force concept, the services must obtain most of their officer candidates from a DOD funded ROTC program requiring some post graduation active service. As now defined these ROTC students agree to put on a uniform and must be physically able to meet the requirements of the service they volunteer for. These requirements restrict the number of potential students that could use grant financial (not debt) aid.

My concept, which I continue to whole heartedly support, is to expand these programs considerably. Instead of restricting the financial support to only those who are physically fit and who will agree to active military service, I would open the categories of completing obligated service, and limit the physical restriction to the category of how the obligated service is to be discharged. For instance, a promising student who does not want to or is physically able to, could discharge his obligation by taking a civilian job in one of the in-house laboratories in a junior civil service assignment. The length of this obligated service would be the same as if they went on active duty.

Another way that this obligated service could be discharged would be if the individual were willing to go into teaching, either at the assistant professor level, or as a secondary school teacher. Again, the obligation period would be the same.

In my view this program would provide a much larger pool of potential scientists and engineers. In addition, it would have an explicit benefit of giving DOD a larger group of young engineers and scientists that at the present time DOD can't recruit successfully. Also, which is probably the most important result, it would provide a pool of properly educated people that would devote a reasonable period to teaching. One of the reasons the U.S. is not graduating more U.S. citizens as PhD's from the center of excellent institutions is the lack of assistant professors and the costs of going to graduate school. Promising four year students opt to go into industry at high pay, then continue on with graduate work at low or no pay. A program of this sort could help alleviate this situation. The cost is modest when compared with alternatives.

To recap: the value given for value received is by paying for undergraduate education, a period of obligated service is required; With the manner of discharging this DOD obligation broadened to other than uniformed service. In addition, the concept of teaching also serves DOD's needs by creating the where with all to prepare and train a greater number of scientists and engineers.

I recommend the committee review the 1982 report written by Dr. Robert Seamans (MIT) and Dr. Lawrence Korb (DOD) and presented to the DOD/University Forum. This report covers the DOD's needs for scientists and engineers, and can be obtained from Dr. Leo Young in the office of Deputy Undersecretary of Defense for Research and Advanced Technology in the DOD.

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

THURSDAY, OCTOBER 3, 1985

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
SCIENCE POLICY TASK FORCE,
Washington, DC.

The task force met, pursuant to recess, at 9:40 a.m., in room 2318, Rayburn House Office Building, Hon. Norman Mineta (acting chairman of the task force) presiding.

Mr. MINETA. This is the second day of 6 days of hearings on the topic Science in the Mission Agencies and Federal Laboratories. Yesterday, we heard an overview of science in the mission agencies and Federal laboratories, and science in the Department of Defense. Today, we will be exploring further the role of the laboratories and science in the Department of Agriculture.

Our first witness is Dr. Michael Crow, assistant director for policy analysis at Ames Laboratory and assistant professor of political science at Iowa State University. He will be addressing the general question of how R&D laboratories have evolved over the past 40 years and what these changes mean for R&D policy.

[A biographical sketch of Dr. Crow follows:]

DR. MICHAEL M. CROW

Michael M. Crow currently serves on the Political Science faculty of Iowa State University and as the Assistant Director for Policy Analysis at the Ames Laboratory, a government owned/contractor operated facility of the U.S. Department of Energy.

A graduate of Iowa State University, Professor Crow received his Ph.D. in science policy from the Maxwell School at Syracuse University. His research focus is in the areas of R&D policy, R&D laboratory management and energy policy. Dr. Crow has previously served as the Director of the National Comparative R&D Laboratory Project at the Syracuse University, as the Assistant Director of the Coal Extraction and Utilization Research Center at Southern Illinois University, and as the Associate Director of the Institute for Mining and Minerals Research at the University of Kentucky. He is the author or co-author of a number of publications and also edited the manuscript *High Sulfur Coal Exports: An International Analysis* (1983) and served as co-editor for the manuscript *Strategic Management of Industrial Research* (1984).

STATEMENT OF DR. MICHAEL M. CROW, ASSISTANT DIRECTOR FOR POLICY ANALYSIS, AMES LABORATORY, IOWA STATE UNIVERSITY, AMES, IA

Dr. CROW. Mr. Chairman, my name is Michael Crow and I currently serve as the assistant director for policy analysis at the Ames Laboratory and teach science and technology policy at Iowa

State University. This morning, my goal is to address the general question of how R&D laboratories have evolved since 1945, as well as the more specific question of what these changes mean for R&D policy. The data I will be presenting was collected under the auspices of the National Comparative R&D Laboratory Project which I directed between October 1983 and February 1985.

The fact that R&D laboratories have evolved and changed since the expansion of Government R&D policy in the 1940's is taken as a given. We have all observed the changes from the largely pure-type industrial, governmental, and university laboratories of the pre-World War II era to the large number of R&D laboratory types operating today. Unfortunately, we have not updated our conceptualizations of these organizations with these changes. It is toward this end that our comments today are directed.

This persistence in sticking with our pre-1940 notion of the institutional framework for R&D organizations—industrial, Government, and university—not only ignores the evidence of drastic organizational change, it also fails to recognize the very dynamic nature of this particular organizational form. In less than 100 years, research organizations have evolved from the small product-oriented industrial technical shops of the 19th century to one of the most diverse organizational populations currently in operation. R&D organizations have changed rapidly as a result of the very dynamic environment in which they operate. With over 11,000 R&D organizations operating in the United States, it has simply become impossible to consider them from the once acceptable industrial/university/governmental framework.

By rethinking the institutional framework of R&D organizations, we may better understand the types of institutions performing the task of knowledge production and also improve our concepts as to how technology changes. Current theories assume that industrial, governmental, and university research organizations each have a particular role and function. These assumptions have become so pervasive that they have kept us from fully understanding the extent to which R&D organizations have evolved. In fact, the R&D organization, pursuing the development of new products and processes guided by market forces, has become a rarity. As a result, we have developed over time the misconception that industrial R&D labs are similar and that, while some are heavily influenced by the Government, they predominantly remain guided by market forces. Such an assumption undermines several of the basic precepts of modern organization theory which tell us that organizations behave as a function of their environment. Given this fact, we feel it is foolish to believe that an industrial R&D organization influenced heavily by both the Government and the market is, in fact, the same type of organization as one operating with influence only from the market.

Given the extensive changes in the level of Government influence affecting industrially owned R&D labs, the changing role of market influences of Government labs, and the wide array of hybrid laboratory forms, we feel that the time has come to reconsider the conceptualization of the R&D organization framework. To address this problem we designed and carried out, under the auspices of the National Comparative R&D Laboratory Project, an ex-

tensive analysis of how R&D laboratories have changed over the last four decades. To capture these differences, a new institutional conceptualization for R&D organizations was designed and tested; the remainder of this paper reviews this effort.

To address the problem of evolution among R&D organizations, a new framework for classifying and conceptualizing these organizations, in this case R&D laboratories, was designed. To capture the nature of the effect of changes in the level of governmental influences, while at the same time considering the effect of market influence on an R&D laboratory's behavior, a two-dimensional configuration was designed which would classify R&D organizations according to their dominant external inputs. Regardless of who owned a laboratory, we felt it was important to first classify R&D laboratories according to the extent to which they were influenced by the Government. Was a laboratory public in the sense that it was heavily influenced by the Government, or was it independent of Government influence? Beyond Government influence, we felt that the extent to which the products of an R&D laboratory were influenced by the economic market would also be useful in capturing laboratory variation.

With our goal being the design of an institutional framework that would capture the changes that had or might occur among research organizations, the nine-celled classification matrix shown in table 1 was developed. We established a theory-based classification scheme for R&D organizations which separates research organizations based on the assumption that an organization is a function of its environment. If we assume that the two dominant environments affecting research organizations are the Government and the market, we separated organizations based on the level of governmental influence affecting that organization by a number of proxy measures, and we separated those organizations based on the level of market influence affecting those organizations.

CLASSIFICATION SCHEME FOR R & D ORGANIZATIONS

LEVEL OF MARKET INFLUENCE (Nature of R & D Products)	LEVEL OF GOVERNMENTAL INFLUENCE: High	Moderate	Low
Generic Product (Low)	Public Generic	Quasi-Public Generic	Independent Generic
Balanced Product (Moderate)	Public Multi-Market	Quasi-Public Multi-Market	Independent Multi-Market
Proprietary Product (High)	Public Market	Quasi-Public Market	Independent Market

Table I

We came up with nine classifications, nine types of research organizations ranging all the way from public generic laboratories, which are laboratories which are heavily influenced by the Government and with only limited influence from the market, ranging all the way to, at the bottom right-hand corner, independent market laboratories, which are laboratories experiencing very low levels of governmental influence and very high levels of influence from the market.

Now you might say to yourself, "Well, 'public generic laboratory' means 'governmental laboratory.' " Well, "public generic laboratory" does not mean "governmental laboratory." It means a laboratory heavily influenced by the Government, that is, producing a product not oriented toward the market, and in that array of organizations what we found was, after surveying these 800 labs, 250 agreed to participate in great detail for us to study them in greater detail. We found that that public generic classification was made up of only about 20 percent Government-owned laboratories, but that the array of organizations producing the types of products which were typically linked to Government labs was actually made up of industrially owned labs, what we call cooperatively owned labs, and a full range of research organizations.

What we found, if you look at the second slide, moving on from slide 1, is that of our 250 study participants—that is, the 250 laboratories that let us in to see what they were doing in great detail—we found a very large number of these organizations classified as public generic labs, only a small number as independent market labs, with a number spread out throughout. Now I'm not certain whether or not the significance of this is as obvious as it is to us, since we have been on the inside. If you look, for instance, at the public market laboratory classification back on slide 1, public market laboratories are laboratories that are heavily influenced by the Government. The results of the classification indicate that each of the R&D laboratories of the various types identified are similar in character, regardless of lab ownership.

CLASSIFICATION OF R&D ORGANIZATIONS BY ENVIRONMENTAL INFLUENCE

LEVEL OF MARKET INFLUENCE (Nature of R & D Products)	LEVEL OF GOVERNMENTAL INFLUENCE: High	Moderate	Low	Row Total
Generic Product (Low)	Public Generic	Quasi-Public Generic	Independent Generic	
Total	121	40	6	167
Row %	72.5	24	3.6	68.2
Column %	89.6	64.5	12.5	
Total %	49.4	16.3	2.4	
Balanced Product (Moderate)	Public Multi-Market	Quasi-Public Multi-Market	Independent Multi-Market	
	4	11	10	25
	16	44	40	10.2
	3	17.7	20.8	
	1.6	4.5	4.1	
Proprietary Product (High)	Public Market	Quasi-Public Market	Independent Market	
	10	11	32	245
	18.9	20.8	60.4	100.0
	7.4	17.7	66.7	
	4.1	4.5	13.1	
Column Total%	135 55.1	62 25.3	32 19.6	

Number of missing observations = 5

Table II

If we move on past the second slide, which gives you some idea of how an array of laboratories in a sort of a test run of this activity might be distributed, and move to the third slide, I know that it's a little bit small but let's look just at research scope. What we did here was, beyond the 250 that gave us detailed information, we actually visited about 35 or 32 of these laboratory sites for extensive onsite case study analysis, and in that I tried to summarize these case study analyses in this particular chart.

R & D Effectiveness Variation by Laboratory Type

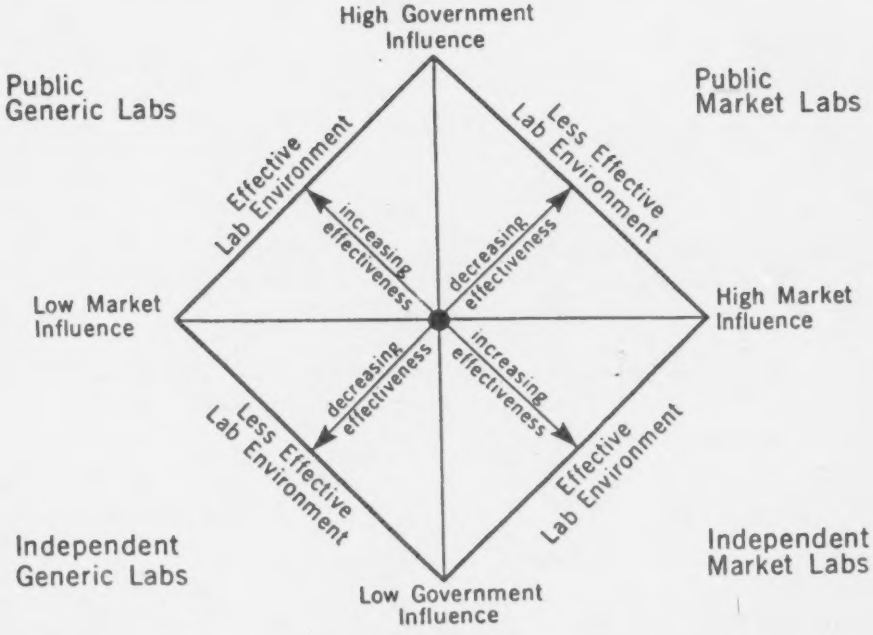

Figure 1

Looking only at research scope, we see, for instance, that public generic labs and quasi-public multimarket labs are the only two types of laboratories that have a national research orientation. Quasi-public generic laboratories, which are laboratories which have a moderate amount of influence from the Government and very little influence from the market, tend to be more regional or, if they are industrially oriented, interfirm in their nature. What this chart implies is that we did find distinctive differences that were consistent among the laboratory types that we were looking at, confirming in fact that our classification technique was capturing the actual evolutionary process that had occurred among this particular organizational population.

We also found, looking at the organizational stability question, that only three of the laboratory types, it turned out, were stable in a sense—stable in the sense of funding, stable in the sense of organizational structure, stable in the sense of planned growth and those types of things. These were the public generic labs, the quasi-public multimarket labs, and the independent market labs. It turns out that if you looked at the archetypical type governmental lab from what we are expecting governmental labs to do, the public generic laboratory classification fits that the closest, and the inde-

pendent market laboratory classification fits the industrial lab the closest. The problem is that ownership—industrial, governmental, university, or whatever—has really nothing to do with any of these classifications whatsoever.

Now the second part of our study was to ask the general question: "How do these various laboratory types, given that we have found that this is a useful means of actually understanding the types of labs that we have, how does their effectiveness vary? Does it vary?"

If you turn to the next slide, the one titled, "R&D Effectiveness Variation by Laboratory Type," I try to summarize a rather extensive effectiveness evaluation there.

ORGANIZATIONAL VARIATION BY R & D ORGANIZATION TYPE

	PUBLIC GENERIC	QUASI-PUBLIC GENERIC	INDEPENDENT GENERIC	PUBLIC MULTI-MARKET	QUASI-PUBLIC MULTI-MARKET	INDEPENDENT MULTI-MARKET	PUBLIC MARKET	QUASI-PUBLIC MARKET	INDEPENDENT MARKET

Table III

What we did was, of the thirty-two case study laboratories, we carried out a four indicator effectiveness evaluation. The four indicators of effectiveness of the labs were, we did what we called a significant accomplishment evaluation. We took a list of significant accomplishments from the each of the laboratories, representing each of the various types that we had. We had each of these significant accomplishments evaluated by a peer committee as to their overall scientific or technical significance. We then went to a second indicator, what we call "general peer review," where we had these 32 laboratories evaluated by the general scientific community as to their overall effectiveness.

The third indicator that we had of effectiveness was what we called strategic constituency evaluation. We asked those people around the laboratories, each of them, "Is this laboratory effective, and if it is effective, how effective is it?" We asked that of each of the groups that, in a sense, were stakeholders in each of these laboratories involved in the case study. Then, finally, we did our own effectiveness evaluation—that is, the interviewing team, the site visit team—of what was going on.

What we found is kind of interesting, and I have tried to summarize it in this graphic. What we found was that laboratories with high levels of governmental influence that also had high levels of

market influence—that is, laboratories which were dominantly influenced by the Government, which were also asked to interact with the market—what we found was that their laboratory effectiveness decreased as the level of market influence increased. Looking at the upper right quadrant, the public market labs were the type of lab that fit in that classification, and you can see that from our evaluation, at least for now, given the nature of the way science policy is put together, that laboratory type operates in a less effective environment.

If you look at the public generic laboratory type—that is, if you increase governmental influence while at the same time not increasing market influence—you tend to increase the ability of those laboratories to operate effectively. Looking in the lower right quadrant—moving in the other direction—if you have a high market influence environment with low governmental influence, what some traditionally consider to be the industrial laboratory environment, what we call the independent market labs, that turns out to be an effective environment. But if, on the other hand, looking at the left quadrant, you have no dominant influence either from the Government or the market, what you find is that you also have a decreasing level of effectiveness.

Now that summarizes generally our effectiveness evaluation. Looking at how that plays out at the next slide, the slide entitled: "Research focus of various laboratory types," what we did was, we arrayed each of the laboratory types on this figure according to how they are oriented—the types of research that they do—not basic or applied. That is too linear of a classification. What we look at is the extent to which they devote their research toward the scientific frontier, what we call the technological frontier, which is the most advanced set of technological options, or what some people call the achievement frontier, what I have listed there as existing technological options.

RESEARCH FOCUS OF VARIOUS LABORAORY TYPES

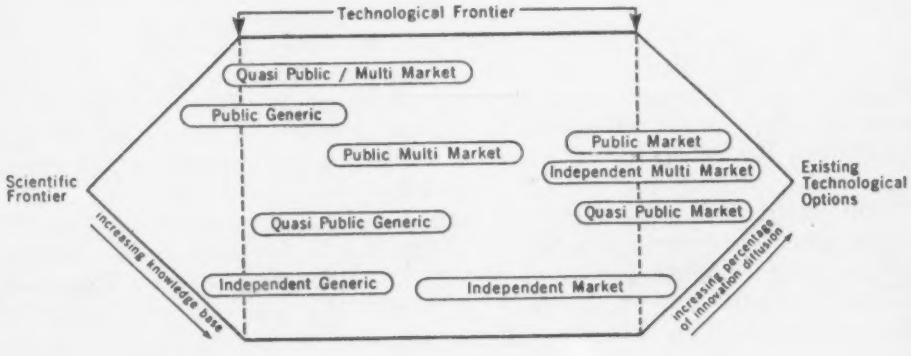

Figure 2

Now remember, of the nine laboratory types that we were able to classify, of the nine types that we captured in our assessment of

how these organizations have changed, only three of those types truly proved to be effective in carrying out their missions—the public generic laboratories, the quasi-public multimarket laboratories, and the independent market laboratories. The other six types on that chart are spread out, and are much less effective than those three.

What that indicates to you is that, if you look at this from a national perspective—and we have a difficult time extrapolating only from 250 laboratories to a national perspective, this is just phase 1 of the study—if you extrapolate that—what that means is that in the area of intermediate applied research, in the area of technology development, in the midrange of the technological frontier—we have a gap. We have an inability to communicate between certain laboratory types, as a result of not having real effective research organizations in that particular arena, operating within that specific arena.

We did look at and consider some of the policy implications of some of our findings, and I won't go into all of them. We have summarized them in a number of comprehensive documents, other than the document that I have presented to the task force, and those are available. The principal document of phase 1 of the study is available through the National Technical Information Service, but let me review some of the points which might be worth considering by the task force.

First, we find that R&D laboratories are not static organizations, static entities which are impervious to change. They are in fact highly innovative organizations which change at rapid rates from an innovative perspective. They change rapidly as a function of Government policy, and it should be remembered that when Government policy is being developed, that the organizations to which these policies are being directed actually do change as a result of those policies. They physically, organizationally, and behaviorally change. I think that's an important point. Policies should be thought of from the perspective that they have more than just an impact on the rate of technological growth or the rate of technological change within a specific industry or a specific sector. They actually cause these organizations to change themselves. They cause evolutionary change, as we have seen since 1940.

Second, we need to seriously consider the question of institutional variation when developing new science or research policies. At present the policies that we have are very generalized. They look at the industrial sector or they look at governmental labs as one block, as one mass of organizations. We are trying to suggest through our new typology that we can't think of them that way. We have got to look at them much more carefully. We have got to consider the conflicting influences of the market and the Government and then think about how that might affect or influence the effectiveness of those organizations to produce the knowledge or the intellectual capital that we are asking them to produce.

Third, as I indicated in my statement, we need to consider the possible effects of increasing the level of market influence on what we call the public generic labs very carefully before we move in this direction on a large scale. Preliminary indicators of phase 1 of our study tell us that public market laboratories and public multi-

market laboratories have a tough time being effective in the U.S. political/economic system. That is, their effectiveness begins to deteriorate as their level of conflict between governmental influence and market influence increases. To some extent, we need to find out why this is a problem and perhaps attempt to address this problem.

Then, finally, my fourth point is that R&D policy initiatives must be cognizant of the influence conflict that I was mentioning just previously between governmental and market influence. We should recognize that Government influence can have a negative effect and a positive effect on the conduct of research, given that we have some understanding of the extent to which these research organizations—what we are actually looking at when we are attempting to implement policy on this range of organizations.

Basically, that is where we have gone thus far in the study. We have been at it for a while, and with that I'll stop.

POLICY IMPLICATIONS OF THE EVOLUTIONARY CHANGE IN R&D ORGANIZATIONS

> "Today science in America is conducted within a framework of institutional structures consisting of research universities, industrial firms, and governmental agencies that evolved in part by purposeful design and in part by historical accident." (Report of the Task Force on Science Policy, Committee on Science and Technology of the U.S. House of Representatives, 1984).

Introduction

Mr. Chairman, my name is Michael Crow and I currently serve as the Assistant Director for Policy Analysis at the Ames Laboratory and teach science and technology policy at Iowa State University. This morning, my goal is to address the general question of how R&D laboratories have evolved since 1945, as well as the more specific questions of what do these changes mean for R&D policy. The data I will be presenting was collected under the auspices of the National Comparative R&D Laboratory Project which I directed between October 1983 and February 1985.[1]

The fact that R&D laboratories have evolved and change since the expansion of government R&D policy in the 1940s is taken as a given. We have all observed the changes from the largely pure-type industrial, governmental and university laboratories of the pre-World War II era to the large number of R&D laboratory types operating today. Unfortunately, we have not updated our conceptualizations of these organizations with these changes. It is toward this end that our comments today are directed.

[1]A complete summary of the findings of this project is presented in the report entitled The Effect of Publicness on Organizational Behavior: Comparative Analysis of R&D Laboratories. This report is available from NTIS (Report number 85-216646).

This persistence in sticking with our pre-1940 notion of the institutional framework for R&D organizations (industrial, government and university) not only ignores the evidence of drastic organizational change, it also fails to recognize the very dynamic nature of this particular organizational form. In less than 100 years research organizations have evolved from the small product oriented industrial technical shops of the 19th century to one of the most diverse organizational populations currently in operation. R&D organizations have changed rapidly as a result of the very dynamic environment in which they operate. With over 11,000 R&D organizations operating in the U.S. it has simply become impossible to consider them from the once acceptable industiral/university/governmental framework.

Rethinking the Institutional Framework for R&D Organizations

By rethinking the institutional framework of R&D organizations we may better understand the types of institutions performing the task of knowledge production and also improve our concepts as to how technology changes. Current theories assume that industrial, governmental and university research organizations each have a particular role and function. These assumptions have become so pervasive that they have kept us from fully understanding the extent to which R&D organizations have evolved. In fact, the R&D organization, pursuing the development of new products and processes guided by market forces, has become a rarity. As a result, we have developed over time the misconception that industrial R&D labs are similar and that while some are heavily influenced by the government they predominantly remain guided by market forces. Such an assumption undermines several of the basic precepts of modern organiza-

tion theory which tell us that organizations behave as a function of their environment. Given this fact, we feel it is foolish to believe that an industrial R&D organization influenced heavily by both the government and the market is, in fact, the same type of organization as one operating with influence from only the market.

Given the extensive changes in the level of government influence affecting industrially owned R&D labs, the changing role of market influences on government labs and the wide array of hybrid laboratory forms we feel that the time has come to reconsider the conceptualization of the R&D organization framework. To address this problem we designed and carried out under the auspices of the National Comparative R&D Laboratory Project, an extensive analysis of how R&D laboratories have changed over the last four decades. To capture these differences, a new institutional conceptualization for R&D organizations was designed and tested; the remainder of this paper reviews this effort.

Recommended Organization R&D Typology

To address the problem of evolution among R&D organizations, a new framework for classifying and conceptualizing these organizations, in this case R&D laboratories, was designed. To capture the nature of the effect of changes in the level of governmental influences, while at the same time considering the effect of market influence on an R&D laboratories behavior, a two dimensional configuration was designed which would classify R&D organizations according to their dominant external inputs. Regardless of who owned a laboratory we felt it was important to first classify R&D laboratories according to the extent to which they were influenced by the government. Was a laboratory 'public' in the

sense that it was heavily influenced by the government or was it independent of government influence? Beyond government influence, we felt that the extent to which the products of an R&D laboratory were influenced by the economic market would also be useful in capturing laboratory variation.

With our goal being the design of institutional framework that would capture the changes that had or might occur among research organizations, the nine celled classification matrix shown below in Table I was developed.

CLASSIFICATION SCHEME FOR R & D ORGANIZATIONS

LEVEL OF MARKET INFLUENCE (Nature of R & D Products)	LEVEL OF GOVERNMENTAL INFLUENCE: High	Moderate	Low
Generic Product (Low)	Public Generic	Quasi-Public Generic	Independent Generic
Balanced Product (Moderate)	Public Multi-Market	Quasi-Public Multi-Market	Independent Multi-Market
Proprietary Product (High)	Public Market	Quasi-Public Market	Independent Market

Table I

Each of the nine laboratory classifications represent the general types of R&D organizations that can be expected to be operating in the complex array of government influences and market influences that affect organizational behavior.

As Table I indicates, there are a number of possible R&D laboratory types. Public Generic laboratories, for instance, might be considered to be the archetypical 'government' R&D lab of the pre-1940 era. These are research organizations which are heavily influenced by the government with an R&D product that is generic in nature, resulting in very little market influence. In contrast, the Public Market laboratory type represents those research organizations which are simultaneously heavily influenced by both the government and the market. Organizational logic tells us that while both of these research organization types are influenced heavily by the government, that the variation in market influence is likely to result in a very different type of organizational behavior.

To test the utility of this new conceptual framework for the array of R&D institutions that currently exist, we classified 250 respondents to an extensive survey of 839 energy or energy related R&D laboratories. Based on these responses the laboratories were classified according to their various levels of governmental and market influence. The results of this classification are shown in Table II. While too preliminary to be representative for all R&D organizations, this classification, and the subsequent analysis of similarities and differences in organizational structure, resource flows, R&D product configuration and research focus, indicates that there are, in fact, a wide range of R&D

CLASSIFICATION OF R&D ORGANIZATIONS BY ENVIRONMENTAL INFLUENCE

LEVEL OF MARKET INFLUENCE (Nature of R & D Products)	LEVEL OF GOVERNMENTAL INFLUENCE: High	Moderate	Low	Row Total

Table II

laboratory types operating in todays policy/market settings. The results of the classification indicate that each of the R&D laboratories of the various types identified are similar in character, regardless of lab ownership.

Subsequent on site analysis of a number of laboratories of each type (32 labs in total) indicated that the method of laboratory classification did, in fact, capture very distinctive differences in structure, resource scope, research frontier, research planning and organizational stability among the laboratory types. Table III summarizes these differences below.

The variation among laboratory types was quite distinctive and indicates that each type conducts its research from its own set of perspectives. The traditional roles of university, industrial and

Table III

governmental laboratories can be seen in the characteristics of the various lab types, but these types have nothing to do with ownership. Public Generic laboratories are clearly based on a 'government laboratory' model of generic R&D products, long range planning, and an emphasis on the scientific research frontier. Of these laboratories, however, fewer than 15% are owned and operated solely by the government. Most are either cooperatively owned and operated or in some cases are owned by industry and financed by the government. In any case, Public Generic Laboratories do have the traits often considered by policy analysts and policy makers to be those of government labs but it is not accurate to call them such. Government owned R&D labs were also found in the Public Multi-Market and Public Market laboratory classifications. Each of these laboratory types behaves with its own individual characteristics, largely as a function of its individual environment. These indi-

istics, largely as a function of its individual environment. These individual laboratory characteristics are consistent among laboratories of the same type regardless of who owns the laboratory.

As a result of our analysis of the 250 R&D organizations involved in the study, it is possible to conclude that we have developed a more accurate conceptual tool for considering the new institutional framework in which R&D is carried out. The classification of R&D laboratories as being either industrial, university or governmental is simply outmoded and in need of replacement.

Today we have research facilities owned by private firms totally financed by the government to produce generic research. Such a research organization can not any more be called a pure industrial research organization than a government financed market oriented facility can be called a pure governmental research organization. The policy arena has become too complex and organizational evolution so pervasive that our 1940 nomenclature no longer applies. This nomenclature is in serious need of replacement and we are offering this approach as a new conceptualization.

R&D Effectiveness as a Function of Governmental and Market Influence

To further test the value of this new institutional framework, we embarked on an effort to evaluate the comparative effectiveness of the various laboratory types. Our basic question was: how does government and market influence affect R&D laboratory performance? This question is, of course, an expansion on the somewhat simpler notion of comparing the performance of a government lab with an industrial lab in a particular area of research. In this case, our desire was to compare the rela-

tive effectiveness of our various laboratory types, giving consideration to the possible reasons behind variations in the relative effectiveness.

The implementation of the effectiveness evaluation involved the extensive study of several labs representative of each of the new types (32 total labs). As a part of this study, four partial indicators of R&D laboratory effectiveness were utilized as a means of gaining some insight into possible variations in performance. These indicators and their measures included:

1) Strategic Constituency Evaluation: The 'stockholders' associated with the activities of each laboratory evaluated, from their individual perspective, the overall effectiveness of the laboratory.
2) General Peer Review: Each study laboratory was evaluated as to its overall effectiveness by at least 30 external reviewers.
3) Significant Accomplishment Review: Each study laboratory identified a number of significant scientific and technical accomplishments produced in the last five years. Each of these were reviewed by at least four external reviewers and an overall evaluation of significant accomplishment outputs was carried out.
4) Case Study Analysis: As a part of the detailed analysis of each of the study laboratories the case study reviewers evaluated the overall effectiveness of the lab. Criteria for effectiveness included 1) funding stability, 2) organizational stability, 3) research planning, 4) new idea generation and 5) general condition of the research environment.

Analysis of the findings of this evaluation indicates that there is significant variation in the effectiveness of R&D laboratories and that much of this effectiveness variation is a function of the various levels of governmental and market influence affecting a given laboratories behavior. The results of this analysis are summarized for ease in interpretation in Figure 1.

As shown, laboratory effectiveness in the production of generic products increases as government influence on the R&D organization increases. As might be expected, effectiveness in the production of

R & D Effectiveness Variation by Laboratory Type

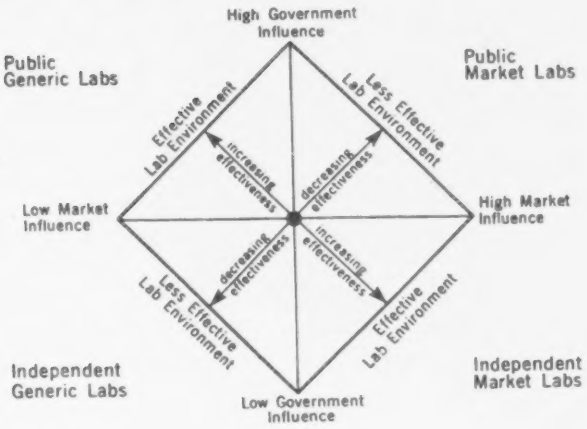

Figure 1

market oriented R&D products decreases as governmental influence increases. Our assessment is that R&D laboratory effectiveness declines rapidly as a function of environmental complexity. In other words, as the government/market influence mix becomes more complicated, the effectiveness of the organization declines. Our explanation for this is that as the influence mix increases in complexity (e.g., the Public Market Laboratory type with high governmental and high market influence) the individual laboratory must deal with a higher level of organizational goal conflict, spend more resources on administration and spend less time in the very important process of research planning. Only Quasi- Public/Multi-Market laboratories were able to balance their competing influences so as to remain effective. All other laboratory types which were not either dominantly influenced by the government

(Public Generic Laboratories) or dominantly influenced by the market (Independent Market Laboratories) experienced a reduced level of measured effectiveness. In addition, those laboratory types with little government or market influence at all (i.e., Independent Generic Labs) also appeared to be less effective. The explanation for this, however, remains unclear.

Policy Implications of Rethinking the Institutional Framework

For the purposes of this discussion, the focus of assessing science policy implications of this reconceptualization is limited to R&D policy. Post-1980 R&D policy in the United States is best characterized as being composed of a number of components. These components include: 1) continued direct support to industry for the conduct of research in areas of national interest and in areas of potential economic growth, 2) general movement of federally financed research and development institutions into a mode where they are more responsive to the market economy and its need for growth, 3) movement toward the development of cooperative centers for research and technology transfer among universities, industry, and government, and 4) R&D tax credits designed to enhance the rate of investment at industrial R&D laboratories.

Considering only the points detailed above as general trends of current R&D policy, the implications of our reconceptualization of the institutional framework for R&D organizations should bring about cause for hesitation, in continuing down the same policy path without careful thought. Consider the implications detailed below with regard to the four policy trends reviewed above.

1) Continued R&D Support to Industry -- The continued direct policy action of R&D funding to industry is based on the assumption that government financing of research in industrial laboratories results in a complimentary integration of the firm's R&D with the government's goals. The basic assumption here is that firms naturally will not invest in research beyond the level of private return and that if the government makes available resources to alter the firm's cost function then the firm will pursue research in areas where it might not normally have been involved.

Our general findings indicate that as firms move away from less complicated environments with very little influence from the government, toward environments which are less directly influenced by their individual market arena, the stability and effectiveness of the R&D laboratory declines. More important than this fact, the fact that government policies for the direct financing of industrial research fail to consider that the addition of government financing to a R&D laboratory with previously low levels of government influence will, in effect, change the nature of that R&D laboratory. This environmental change, it is hypothesized, results in structural and behavioral changes in the R&D laboratory which cause it to become a different type of R&D laboratory. As a result, the rate and direction of scientific technical change previously occurring at the laboratory, in all likelihood, will change to the extent that there is actually an effectiveness decline.

The general findings and subsequent hypotheses resulting from the National Comparative R&D Laboratory Project, therefore, do not support the notion that increasing direct R&D support for industry in fact moves

us toward improving rates and direction of technical change. For instance, it should be noted that Public Generic laboratories, which have the lowest levels of market influence and the highest level of governmental influence, operate the most effectively on the technological and scientific frontiers. It is research which is directed toward these frontiers that results in the revolutionary type of technical breakthroughs desired by many. At the other end of the spectrum, Independent Market laboratories, in environments with low governmental influence and high market influence are also capable of working on the technological frontier. An increase in governmental influence, however, among these laboratories results in a movement away from the technological frontier toward a focus on existing technologies only. Figure 2 illustrates the research focus of the various laboratory types and further details more effective from less effective laboratory types.

RESEARCH FOCUS OF VARIOUS LABORAORY TYPES

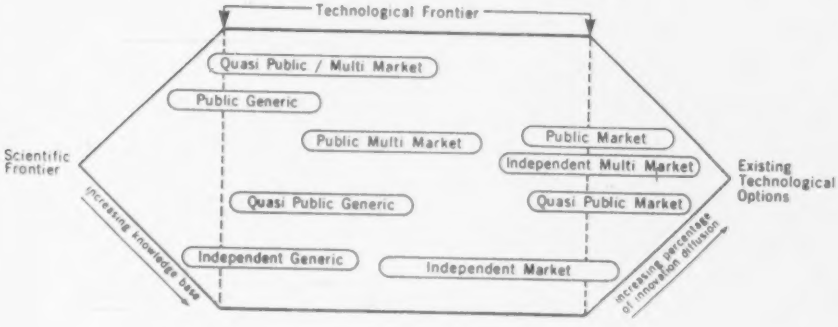

Figure 2

A national R&D policy which assumes that direct financing of research in industrial R&D laboratories will lead to the most effective production of either revolutionary technical change or evolutionary technical change should be cognizant of the implications of our findings which indicate that it is possible that relatively small changes in the level of governmental influence and in the distance a laboratory moves away from its traditional markets could result in very drastic reductions in an R&D laboratory's effectiveness.

2) Movement of 'Public' R&D organizations Toward Market Directed Technical Change -- In the last several years, there has been an outcry for "government laboratories" to be redirected to meet the science-based technical change/economic growth needs of our stagnated economy. The focus of these policy changes has been largely directed toward the Public Generic Laboratory type. As the federal government owns many of these laboratories and finances the rest it has been the desire of many federal policy makers to apply the vast scientific development capabilities available in these institutions to the technical development needs of industry.

The implications of a policy of this type are quite significant. To begin with, Public Generic laboratories appear to have a unique role among the nine laboratory types studied. These laboratories have a national research orientation, a focus on revolutionary technical change, a long-range planning horizon, and a focus on the scientific and technological frontier. In addition, this laboratory type is both stable and among the most effective.

With this background, it is our opinion that Public Generic laboratories in their current environmental setting are quite effective in the production of revolutionary technical change which is not directed toward the needs of any particular industry, but is directed toward particular technological applications. As shown earlier in Figure 2, the production of research and development directed toward the scientific and technological frontier is more effectively carried out in Public Generic R&D laboratories. It is our assessment that as a result of high levels of governmental influence, combined with the lack of market influence these R&D laboratories are able to pursue research agendas with some independence and distance from direct market influence. Our conclusion is that research which might not normally be conducted, due to market influence and constraints, is carried out. Furthermore, this research appears to be both effectively carried out and significant in its value.

The movement of these laboratories into environmental settings with increasing levels of market influence could result in drastic changes in effectiveness and also in the research frontier at which research is conducted. Assuming that governmental influence remains the same and market influence is increased, the laboratory types already existing under these environmental constraints indicate that research effectiveness could drop drastically and that the research focus would move away from the scientific frontier. As a result, from a national policy perspective, the nation's ability to pursue research beyond evolutionary development of existing technologies would be greatly reduced.

3) Development of Cooperative Research Centers -- For some time, it has been the policy of the National Science Foundation and other groups within the government to attempt to stimulate the development of industry/university or university/government cooperative research centers. The assumption here is that development of such cooperative research activities will results in enhanced rates of technical change. Again, this policy assumes that the subsequent environment of the various organizations participating in these cooperative activities will only be positive. Some of the findings of this study indicate that movement toward conflicting market and governmental goals can result in a number of problems. As a result, the development of cooperative research centers as a national policy should be pursued quite carefully.

The objective of any cooperative activity should be the development of an environment of balanced influences where governmental influence is checked by market influence. In addition, and as in the case of Quasi-Public/ Multi-Market laboratories, there must also be the development of a self-determined research agenda. It is through the development of the self-determined research agenda and later the acquisition of resources from either the market or the government that research effectiveness can be maintained. In addition, many of the cooperative activities that have developed in the last several years have grown out of the Public Generic Laboratory type. The movement of these laboratories to new environmental states can reduce our national capability to conduct research directed toward the scientific and achievement frontier. This should be considered in any and all potential policy actions along the lines of cooperative research.

4) R&D Tax Credits -- R&D tax credits are designed to improve the internal calculus of the industrial firm for conducting research and development activities. The hope is that a tax credit will provide sufficient stimulus to permit industrial firms to conduct research, with their own resources, above and beyond that which they might normally have decided to pursue. This general policy seems to have some of the same problems as many of our national R&D policies. To begin with, the assumption is that industrial research laboratories are the principal means through which science-based technical change is produced. The assumption is that if we provide tax incentives to increase the rate of R&D investment in industrial laboratories, then we will subsequently be able to improve the rate and direction of science-based technical change. While is it probably fair to say that R&D tax credits could potentially have an impact on Independent Market Laboratories that exist within an environment of low government influence and high market influence, the same cannot necessarily be said for industrial laboratories that exist in other environments.

It is our assumption that ownership does not predict behavior, but that environment predicts behavior. As a result, this policy, which is directed toward laboratories based on ownership, fails to recognize the fact that the impact will vary as the environment of the laboratory varies. The determination of the nature of the various impacts that such policies might have in various environments is beyond the scope of this study, but a range of impacts can be expected with not all of those impacts necessarily being positive.

Summary

We began this presentation with a general dissatisfaction with the existing conceptualization of the institutional framework for R&D organizations. Suffice it to say that we found the classification nomenclature of industrial, governmental and university R&D organizations to be sorely outmoded. Not only does this conceptualization inaccurately depict how R&D laboratories have evolved through time but it also has adversely affected the process of science policy analysis through its associated organizational behavioral assumption.

Having thrown out both the baby and the bathwater we suggest a multi-dimensional classification scheme for separating R&D organizations according to variation government and market influence. It turns out that this type of environmentally based classification scheme proved to be very useful in identifying nine distinctly different R&D organizational types. These various types of labs capture in a simple way the new array of institutions that makeup the institutional framework for R&D organizations. As might be expected, each of these R&D organization types behave in a prescribed manner, only in this conceptualization the behavioral inputs are based on environmental inputs more likely to influence behavior than ownership alone.

We realize that this effort is very preliminary and that there is a need to test this new framework on a broader scale. In that regard, it is time that we move in this direction and consider on a comprehensive basis the reconceptualization of the institutions performing our societies knowledge producing role. Continued reliance on outmoded theories and assumptions in a policy area of this importance can only add to frus-

tration. Before we can determine how to improve the output of our research organizations we must first understand what they are and how they might react to any action of the government. History has already taught us that these organizations change rapidly. We should learn from this experience and plan the evolutionary development of R&D organizations rather than leaving it up to a series of 'historical accidents'.

BIOGRAPHICAL SKETCH

MICHAEL M. CROW

Michael M. Crow currently serves on the Political Science faculty of Iowa State University and as the Assistant Director for Policy Analysis at the Ames Laboratory, a government owned/contractor operated facility of the U.S. Department of Energy.

A graduate of Iowa State University, Professor Crow received his Ph.D. in science policy from the Maxwell School at Syracuse University. His research focus is in the areas of R&D policy, R&D laboratory management and energy policy. Dr. Crow has previously served as the Director of the National Comparative R&D Laboratory Project at the Syracuse University as the Assistant Director of the Coal Extraction and Utilization Research Center at Southern Illinois University and as the Associate Director of the Institute for Mining and Minerals Research at the University of Kentucky. He is the author or co-author of a number of publications and also edited the manuscript High Sulfur Coal Exports: An International Analysis (1983) and served as co-editor for the manuscript Strategic Management of Industrial Research (1984).

BARRY BOZEMAN

Barry Bozeman is Professor of Public Administration and Director of the Technology and Information Policy Program at Syracuse University's Maxwell School of Citizenship and Public Affairs. Bozeman teaches courses on R&D management, technology policy, and organization behavior. He is currently conducting research projects on corporate strategies for R&D, the impact of public policies on R&D, technology transfer, technoligcal innovation in manufacturing production processes, technological forecasting for robotics, and technology assessment of synfuels energy technologies.

Bozeman is the author or co-author of several books on public management and R&D including, most recently, Strategie Management of Industrial R&D (1984), Investments in Technology: Corporate Strategy and Public Policy (1983), and New Directions in Public Administration (1984). He has contributed articles on R&D policy and organization behavior to many academic and professional publications. Recently published work has dealt with tax incentives for R&D, R&D joint ventures, measuring the effectiveness of public and private R&D labs, use of scientific and technical information in organization decision-making and bureaucratic structures for science and technology policy.

President of the Academy of Management's Public Sector Division, Bozeman is also a member of the American Association for the Advancement of Science, American Society for Public Administration, and the Association for Public Policy Analysis and Management. He is on the editorial boards of The Urban Interest, American Review of Public Administration, Knowledge: Diffusion and Utilization, Administration & Society, and Journal of Accounting and Public Policy. Bozeman has

served as a consultant to a number of private firms and to a variety of federal agencies, including the National Science Foundation, Office of Technology Assessment, the Department of Energy, National Institutes of Health, General Accounting Office, and Oak Ridge National Laboratory.

Before joining the faculty of the Maxwell School, Dr. Bozeman served as Scholar-in-Residence at the National Science Foundation's Division of Information Science and Technology, and was on the faculty of Georgia Tech. In 1983, Bozeman was Visiting Professor of Science Studies and Management, Virginia Polytechnic Institute and State University.

DISCUSSION

Mr. MINETA. Dr. Crow, thank you very much.

First of all, let me, in taking that quote from our own committee as it relates to "purposeful design and in part by historical accident," do you have any idea as to which outweighs the other? Were we really more purposeful or is this whole thing 80 percent accident, where we are right now?

Dr. CROW. I would say that, given that Federal science policy and Federal research policy has not considered the institutions themselves—I mean, the institutions have evolved as a function of their ability to cope with these different environmental influences—I would say that it's predominantly—our array of organizations is more accidental than purposeful, in the sense that we have not sat down and said: "What type of institutions do we want?" In fact, yesterday in some of the discussions there was sort of the hue and cry of: "What type of organizations do we have?" Well, no one could answer that question. There was the hue and cry of, "Well, what can we expect these different organizations to do?" Well, no one could answer that, either.

I think that's an indicator of the fact that there has been a fair amount of random evolution, a fair amount of accidental evolution—you might say—in that there has not been a systematic institutional sort of thread moving through science policy or through research policy. In our attempt to go out and capture how these organizations have evolved, I think we definitely found that.

In that "public generic" classification, for instance, I visited research facilities 100 percent owned by an industrial firm, 100 percent financed by the Government, producing nothing to do with that firm whatsoever, producing nothing to do with the markets of that firm, just producing knowledge. Now do you call that an industrial lab? Do you call that a Government lab? Well, we say you call it a public generic lab. It's heavily influenced by the Government. It's producing a non-market-oriented product, so it is not so influenced by the market, and it is something which has just been allowed to evolve.

If you look out along the array of organizations, I know even within the laboratory that I am a part of the executive council of, given the lack of purposeful policy direction, sometimes I think we set our own course and we evolve on our own. You multiply that by 12,000 organizations out there, and you have got a lot of different entities running around.

So in answer to your question specifically, we are trying to now play catch-up baseball. We are trying to figure out what has happened since 1940. What are these institutions that we have that we rely on so heavily? As Congressman Brown said yesterday: "What do we do with a Jet Propulsion Lab when all of a sudden there is nothing for them to do relative to the Apollo project or planetary exploration? What do we do with this organization?"

Well, first we better have some idea of what it is and what it isn't, and so it has been accidental.

Mr. MINETA. Why was it that your survey was restricted or at least was predominantly energy and energy-related R&D labs?

Dr. CROW. I think because we could only raise $50,000 to do it.

Mr. MINETA. Does that skew what happens in your study?

Dr. CROW. What we have done since we put this together, we think that there would be some change if we increased the organizational population beyond the 839 energy or energy-related R&D labs that we looked at. We think there would be some variation, but not a tremendous amount. We think we would have to modify some of our preliminary findings but not a tremendous amount, so there is a slight skewing but we don't think that it's heavy.

The reason we focused on energy labs was predominantly for the effectiveness evaluation. The effectiveness evaluation was very complicated to implement, and we needed some continuity running through the labs. Previous studies in Europe done by the Science Policy Research Unit at the University of Sussex indicated that the best way to look at research organizations is to at least have some commonality when you're getting started. To have undertaken a more comprehensive evaluation of the larger population would have taken a lot more money and a lot more resources than we had available, given that we had to get our money from different sources, also. It meant that there was some orientation of those sources.

Mr. MINETA. In terms of your summary, talking about the nine classifications, I am wondering whether or not these nine classifications are what you have, the conclusions you came to, on looking at the total array of the structures out there.

Dr. CROW. Well, we built this array from organizational theory. What we did was, organizational theorists in the project went into organizational theory and decided that what we now know about organizations, the best way to classify organizations is based on their environment, based on their environmental influence, because it is the indicator of how these organizations are going to change. It is the best predictor of organizational behavior. Environment is the best predictor of human behavior, often. Environment is the best predictor of organizational behavior. So in that regard we feel that this particular typology that we have put together here and any extrapolations of it, or making it more precise, is in fact a means of capturing organizational evolution that has occurred in the past but also organizational evolution as it occurs in the future.

Mr. MINETA. Now what about, in terms of the structure that you have talked about here? Does that template fit whether it's a scientific R&D lab, maybe even devoted to basic R&D or applied R&D? Is it different as it relates to a medical R&D lab or social, taking into consideration more social-type issues?

Dr. CROW. We would probably limit it to, and the way that we designed it was to limit it to organizations which were actually involved in the conduct of physical science or engineering-related research, more than, let's say, a policy sciences research unit somewhere, that type of thing. We're talking about what you would typically think of as a lab.

Now they can range from lots of different types, of course. We think that there is some general applicability of this particular typology. Basic and applied research, there are both basic and applied generic products. I know that at the laboratory that I am a part of, we produce generic products—that is, not directed to the

market—that are extremely basic and are consumed in the general intellectual literature. We also consume products that are physical themselves. We produce techniques for the production of highly specialized materials, totally unique materials, and we transfer that knowledge—not that technology—we transfer that knowledge generically, not to any specific market purpose, so we think that it does have some general applicability to the population of research organizations.

Mr. MINETA. Now according to your model, Dr. Crow, a program such as the Small Business Innovative Research Program would be counterproductive in small laboratories which were previously under high market influence, and I'm wondering if you have any evidence to——

Dr. CROW. Well, you're talking about—I mean, what I know and the people that I have dealt with relative to that program are generally very small firms, sometimes two or three guys running around who have got an idea. They are generally, at least from the people that I have dealt with—and maybe some that you have dealt with are different—but they are not of an organizational size yet to be classified what we call a research laboratory.

There is sort of a minimum threshold to which this applies, but let's say it's a small firm of 20 people or something like that. To that extent, if they are operating on their own from a market perspective, dominated by the market, that's probably hard to say. I mean, if they are at that threshold of just getting started, perhaps they are actually dominantly influenced by the Government and then secondarily influenced by the market.

One could say, however, that given some of our general findings, that if they were large and the Government did come in—they were dominantly influenced by the market—the Government did come in and increase its level of influence on that organization, we would from our results tend to think that their level of effectiveness would decline. They would now attempt to try to deal with two conflicting types of influences.

Now that doesn't mean that necessarily that's the way it has to be. What that means is that, given the way we look at institutions, given the lack of an institutional threat running through some of our policies, what that means is that is what would likely happen.

Now let me take it to another example. One of the laboratories that I visited that was a public multimarket laboratory had previously been in an environment similar to public generic laboratories. They were a major research facility, a couple of thousand employees, and they were being forced by their particular government to increase their level of market-related activities. They were actually becoming more heavily involved, increasing their level of market influence on their organization.

Well, as they did that they changed in their character. You could see how their organization had changed. You could see how their structure had changed. You could see the extent to which their planning process became more and more short term, the extent to which their planning process became more and more linked to the market, and as that happened their level of effectiveness, as we measured it, decreased. In fact, they would also agree that their

level of effectiveness had drastically decreased from their previous setting.

Mr. MINETA. Dr. Crow, we have a call of the House right now but I am wondering, just very quickly, what about the relative sample size, the fact that you have 32 laboratories?

Dr. CROW. We feel that, given——

Mr. MINETA. Is that really a large enough spread to be able to give you a good idea, in terms of your confidence level, of the testing of those 32 labs?

Dr. CROW. In case study analysis, things like levels of statistical significance and confidence levels and so forth are difficult to state. We think that 32 case studies—given the organizational population that we were looking at, 839 laboratories, of which we had significant information on 250—we think that the 32, given the way that we selected them in each of the laboratory types, does give us the type of confidence in our results to make some of the statements that we're making today.

Mr. MINETA. Dr. Crow, you will be able to stay right now?

Dr. CROW. Sure.

Mr. MINETA. Because we have to go over for a vote, and so the task force will stand in recess for 15 minutes.

[Recess taken.]

Mr. FUQUA. Mr. Brown, do you have any questions?

Mr. BROWN. Dr. Crow, your analysis is, I think, going to be very helpful to us as we look at the matter of research laboratories. There are so many of them. You know, just the Government labs, we are told there are 700 or 800 of them, and unless you can put them in some sort of conceptual framework, it's hard to deal with. I wonder if you could give us some examples that help to define the categories that you have set forth in your chart here?

Dr. CROW. In the public generic laboratory type, some examples—and due to the nature of the effectiveness evaluation, I will probably on a couple of them just give you categories—within the study, if you read the whole study, they are anonymous in the study, the 32 actual case studies. In public generic labs, though, we had, for instance, Government-owned, contractor-operated research facilities of large and small size. We had, in public generic laboratories we had an industrially owned, 100 percent financed by the Government research facility producing a nonmarket product, a product totally for the generic consumption from a knowledge perspective. We also had Government-owned, Government-operated research facilities in the public generic type.

Quasi-public generic laboratories included basically groups which pursued Government funding from a contractual perspective. They weren't necessarily federalized facilities like the public generic laboratories. They were facilities that chased Government money and also had a little bit of industrial money on the side.

I can go through who some of these were, public generic laboratories. For instance, there was the Radiation Laboratory at the University of Notre Dame. That's a research facility on the campus at Notre Dame University which is owned by the Government, operated by the university. We know a lot about those.

Also a public generic laboratory: McDonnell-Douglas Corp. Research Facility in St. Louis, MO, 100 percent owned by the firm,

100 percent financed by the Government, producing a product not related to the McDonnell-Douglas market line, producing a product not related to the operating companies of that particular corporation.

Quasi-public generic: the Accurex Corp. in Mountain View, CA was an example of that. That was a particular laboratory which, like I said, chased Government funding. I am not saying that in a negative sense. That was their business. They were in a research business. The Cyclotron Research Facility at the University of California at Davis.

Independent generic laboratories: the Polymer Processing Institute at the Stevens Institute of Technology in Hoboken, NJ. I mean, there you have a facility located at a university with industrial and university personnel, funded not by the Government, funded by the university and various industrial grants, but industrial grants that had—they weren't to produce a market-oriented product. They were just to produce knowledge. That's an example.

Public multimarket laboratories, there weren't very many of those, and the best example was some of the laboratories in the South Dakota State Geological Survey. I'm talking about places that we actually had as our case studies, places that were actually visited, not just the 250 which answered.

The quasi-public multimarket laboratories, the best example there is the General Atomics Corp. in San Diego, CA—GA Technologies, formerly owned by Gulf. That particular laboratory and that particular laboratory type produce a product which is both directed toward the market—a very heavy, not heavy but moderate market influence—and moderate nonmarket influence, moderate Government influence. It turns out that that particular laboratory type was very effective in what it did. We felt that it was effective because those laboratories were self-determinative. They set their own agenda. They sold their research programs to everyone because everybody wanted them, and that's an example of that particular activity.

Independent multimarket laboratories, here we have very little governmental influence but we have a product being produced for both market and nonmarket end uses. Now I don't think you were here when I was describing what that mean, but we call those environmental influences. An example of that was the Ashland Oil research facility in Ashland, KY. They were attempting to produce a product, both a generic product and a market-oriented product, but they were independent of Government influence.

Public market laboratories, and these laboratories had a very difficult time, very difficult: heavily influenced by the Government, heavily influenced by the market. I'll give you two examples. One was the U.S. Bureau of Mines' research facility in Spokane, WA. That particular research facility produces a product which is essentially for the regional mining industry; that's their orientation.

Quasi-public market laboratories: there I will give you an example of the General Motors-Allison turbine research facility in Indianapolis, IN. Here you have a research facility producing a product which is for the market but at various stages of their product development activity you've got the Government funding the intermediate-range research, GM funding the basic research, and the

Government and GM splitting the cost of the development activities. That in this particular case caused some influence conflict between the Government and the market.

Independent market laboratories, that's your bastion of archetypical industrial firms right there. Let's see. Who did we visit there? We looked at the Kaiser Aluminum Co. facility in Pleasanton, CA, as an example. Typical, what you would think to be your prototypical industrial research laboratory; almost an abhorrence of Government influence. "We don't want too much Government money, maybe just a few projects here and there."

Mr. BROWN. When you use the term "market," are you exclusively referring to the private market and not including the public market?

Dr. CROW. I'm including public and private market.

Mr. BROWN. So that a laboratory like Los Alamos, whose product is, we'll say, the Defense Department—they design nuclear weapons—you would describe that as a public market oriented——

Mr. CROW. Well, Los Alamos wasn't 1 of our 250, or I could give you a better answer.

Mr. BROWN. You didn't categorize it?

Dr. CROW. For one, their only product is not that particular thing. They probably have a balanced-type product. They probably are a public multimarket facility. The proprietary nature of the product, which is what makes it have a market characteristic—and I think your point is very good that there are proprietary markets both in the private sector and the public sector——

Mr. BROWN. Correct.

Dr. CROW. The U.S. Coast Guard research facility, working primarily on engine development and other types of things in Groton, CT, is an example of a public market facility.

Dr. BROWN. How would you describe the National Bureau of Standards, which was our first general-purpose research facility?

Mr. CROW. You're asking me to guess, because I have to guess as to what all of their products are and what their dominant orientation is, but what I know about their dominant orientation is that they are probably a public generic facility. In fact, their chief economist, Gregory Tassey, put together the article from which I take the nomenclature of generic technology research and what he calls also infra-technology research, and he has spent some time looking at NBS and its role, so they are probably a public generic research facility although, you know, they've got things going on in Colorado and all over that I don't know a lot about.

Mr. BROWN. Well, the facility in Colorado is probably closest to the public generic research thing.

Dr. CROW. You're hitting on another point. If you look at a specific organization like the National Bureau of Standards, we couldn't classify the organization. We would have to go to their distinctive laboratory units, and I think that one of the problems in some of the generalized science policies is that they assume that all of the units within a single agency are close to being the same. Well, they're not.

We did look at, if you look at, let's say, a company like Gulf, Gulf has 38—or did, before they got wiped out or whatever happened to them—they had 38 research facilities. Each of those research facili-

ties are doing a different thing, and each of them would have to be classified in this typology independently. So some of the NBS—I would say most of the NBS facilities would be public generic type, but there might be some that I'm not aware of that aren't.

Mr. BROWN. Thank you very much, Mr. Chairman.

Mr. FUQUA. Mr. Lujan.

Mr. LUJAN. Thank you, Mr. Chairman. I'm sorry that I'm late. There is a correlation here that is rather interesting. We are all looking for stability, you know, and doing the right thing at the right time. It is interesting that all of those that by type of technical change pursued are revolutionary, also are stable, and those are the only ones.

Dr. CROW. Well, in the independent market I think I say that they are both revolutionary and evolutionary, do I not?

Mr. LUJAN. Yes. Yes, you do, but it includes the revolutionary portion.

Dr. CROW. Yes. It is an interesting——

Mr. LUJAN. Give me—I'm sorry I was late—what are you talking about when you're talking about "revolutionary"—just whole new products, whole new——

Dr. CROW. No, it's an orientation. In the larger things that I have put together, in the literature there are two dominant types of technical change which occur within research organizations. There is technical change which is, in a sense, search-induced. That is, the laboratory goes about its business by looking at the possible array of alternatives to any particular general question or specific question and searches, from that possible array of technological options, for an option that can be applied to a specific activity, or they actually try to develop that option. They go through a searching process.

The other type of technical change which has been talked about quite a bit by the economist Paul David is what is called local neutral. That is, it is evolutionary in the sense that it is directed toward existing technology and moving existing technology—most technical advance takes place of that type—moving it along step-by-step, taking the light bulb and making it better from what Edison had in 1878. That's local, neutral, evolutionary change. That's the separation.

Now these are broad course separations that we're talking about here. That doesn't mean that each of these laboratories, that that is all that they do. It means that is their dominant orientation, but those are some of the differences. For instance, the laboratory that I am associated with is probably a public generic laboratory involved in revolutionary type change. We are not looking at specific technologies. We are looking at the search process for entirely new technologies.

Mr. LUJAN. So you would then say, if you look at the mission—you were talking with Mr. Brown about Los Alamos, and I know you didn't go there——

Dr. CROW. Right.

Mr. LUJAN [continuing]. But you would know the mission. They were revolutionary in the Manhattan project times when they were looking for a whole new way of doing things, and now—if you just take that, the weapons part of the business—

Mr. CROW. Right.

Mr. LUJAN [continuing]. And now they are evolutionary because of ways to make them go faster and more accurate and that sort of thing. Is that your——

Dr. CROW. That's a good analogy. Let's not pin it on Los Alamos.

Mr. LUJAN. No, no. I understand that. No, I was just talking about that particular——

Dr. CROW. Yes, that's a good analogy. That technology, when it was initially developed, when it moved from science to technology, was what the literature generally calls the revolutionary process, and since then it has been an evolutionary process.

Mr. LUJAN. Why are revolutionary ones more stable? Is it because when a company puts money into—basic research I guess would be more revolutionary than applied science——

Dr. CROW. Not necessarily, but——

Mr. LUJAN [continuing]. That they were going to put up $25 million and we're going to forget about it, you know, not return?

Dr. CROW. What you're looking for is the linkage between stability and——

Mr. LUJAN. Yes.

Dr. CROW. It's hard to say whether or not the two are linked. They are independent variables. I think the more important variable is that each of those three laboratory types have the following characteristics. In the public generic laboratory types you have what I call minimal environmental influence conflict. You do not have a conflict going on within the laboratory structure itself in trying to deal with these conflicting influences of the market and the Government.

In the case of the quasi-public multimarket labs, you have the only laboratory type of all of the nine which exists in a highly balanced environment where Government influence and market influence are relatively the same. It is a balanced environment and then also they are determining their own, they are setting their own agenda. Then finally in the independent market you've got the market influence as the dominant.

Now what happens as you move around that and change that influence perspective, you change the ability of those organizations to remain stable. They are highly conflict-oriented organizations. The public market laboratory organizations were organizations that were highly politicized in their research operations. They were highly—they had large administrative structures devoted to managing this complex environment. They were devoting larger percentages of their resources to what I call environmental scanning and environmental management, trying to deal with these conflicts, whereas public generic, independent market, and the one in the middle weren't doing that. What that meant was that they were able to move on to some of these search-type technical change activities and also they were much more stable type organizations.

Mr. LUJAN. Could you draw the conclusion, then, that in our authorizations that we refrain from managing departments by saying, "You will develop a better battery, you will develop this kind of engine, you will develop the different things," that we direct that agency to do that? Can you draw that conclusion from——

Dr. CROW. Not that conclusion, because to say, you know, "Develop us a better battery," well, you know, there is a lot of different ways that one could go relative to that. To say, "Develop me a better battery industry in eastern California," or something like that——

Mr. LUJAN. Or in New Jersey.

Dr. CROW [continuing]. Wherever, now that's a different question, because then the market influence then dominantly comes to play. I mean, if you're just going to develop a battery, there are a lot of things related to that, if you develop yourself a generic battery, but if you're saying to someone like Oak Ridge National Laboratory, "Help develop the economy of the State of Tennessee," you better do that very carefully. You better think about that very carefully because that particular effect on that particular institution is not going to be minor. It's going to be significant, and I think we need to think about quite a bit more this institutional variable. I guess my dominant point is that the institutional variable in most of your policy development activities, most of the Congress' policy development activities, it is considered to be exogenous. It's outside. Well, it needs to be brought inside. It needs to be considered, and we need probably a lot more information than what I'm giving you here to be able to make some firm type statements as to policy A or policy B.

Mr. BROWN. Would the gentleman yield to me at that point?

Mr. LUJAN. Yes.

Mr. BROWN. The issue here is fairly fundamental. The thrust of what you're saying is that if we take a public generic research institution, for example, and try and move it in the direction of a public market, we lose efficiency.

Dr. CROW. According to the ones we looked at, drastically.

Mr. BROWN. Yes, and yet we have some examples of extremely efficient or productive private research laboratories which combine these functions. I am thinking of Bell Labs, for example, which combines the characteristics of independent generic research, relatively unfettered, looking at opportunities in the scientific world, and then it has as part of its components, independent market, which looks at the potential market opportunities for specific kinds of applied science, and they seem to benefit from being within the same institutional framework, which I gather is fairly carefully managed to promote interaction of the various aspects of it.

I am wondering if this doesn't lead us in the direction of concluding that we don't want to distort an institution which is doing well as a public generic research institution but we might want to link it with something with a different mandate that is more oriented toward the market, if that's the direction that we want to——

Dr. CROW. If I was thinking in that direction, which we're just now getting to the stage where we're going to do that, that's probably a good place to start, and that is to begin to think about the different roles that these types of institutions might assume and then look and say to yourself, "Okay, do we want some public market laboratories?" In Europe there's tons of them. They're all over the place, lots of European industrial research institutes, funded by the Government, that are essentially taking care of

market failures and doing research for particular industrial sectors.

If that's what we want, if we want some public market laboratories, we need to think about those influence conflicts that naturally will occur between the Government and its policies and the market and its natural tendencies, and perhaps think about what are the best types of institutions that can maybe perform in that arena or specially design institutions that can better perform than perhaps the ones that we have there now.

Mr. BROWN. Well, the problem we're running into here is illustrated by the so-called Keyworth Initiative to help the steel industry. They want to link some very good public generic laboratories with the needs of—we might call it an ailing industry——

Dr. CROW. You might call it that.

Mr. BROWN [continuing]. And see if there can't be a fruitful interaction. Now that's the kind of judgments that we have to make. What is the best way of harnessing two disparate kinds of activities in a way that will not degrade the efficiency of the public generic laboratory but which will help to solve the problems of the ailing industry, if it's appropriate to solve it? Now we're not clear in what circumstances it is appropriate to solve it in every case but we need, if we decide to, to do it in the best possible way, it seems to me.

Dr. CROW. Right, and I think that what we have to search for are those special—either special institutions that can operate in these environments that we all know exist out there, or the type of bridging mechanisms that you are talking about between the already effective public generic lab and the already effective independent market lab. There can be bridging mechanisms without pulling either one of them away from their already stable, effective settings, and those are the types of things perhaps that one needs to think about.

Now perhaps I am overgeneralizing here because you're taking us way out into a range of institutions that— personally I don't know a lot about the Bethlehem Steel research facilities, or United States Steel, those types of things. I don't know where they might—what type of institutions they are. I don't know if they are independent market research facilities themselves. Maybe someone else does.

Mr. LUJAN. Let me ask just one final question. I know that we're limited in time, but to understand, what do you mean by "stable"?—stable funding, people generally remain at the laboratory, or what——

Dr. CROW. We looked at stability over a number of variables. One variable had to do with funding patterns, looking not only at funding decline, at organizational patterns, at turnover patterns within the organization from a turnover perspective, at their planning patterns, how they planned, over what period did they plan, and to what extent did they stick within their at least generalized research plans, not that research organizations can plan always what they are going to do, but the extent to which they were able to do that. Also, stability as a function of leadership roles within the organization—there were a whole range of variables that we looked at.

Mr. LUJAN. Thank you.

Thank you, Mr. Chairman.

Mr. FUQUA. Dr. Crow, thank you very much for being here today. We appreciate your contributions.

Dr. CROW. All right. I would be happy to answer any other questions that you might have.

Mr. FUQUA. We may have some written questions that we may wish to submit to you for answer.

Dr. CROW. OK.

[Answers to questions asked of Dr. Crow follow:]

ENERGY & MINERAL RESOURCES RESEARCH INSTITUTE

IOWA STATE UNIVERSITY Ames, Iowa 50011
123 Office & Lab Building
(515) 294-2785

RECEIVED
OCT 25 1985
COMMITTEE ON SCIENCE
AND TECHNOLOGY

October 21, 1985

Congressman Don Fuqua
Chairman, Committee on Science & Technology
US House of Representatives
Suite 2321 Rayburn House Office Building
Washington, DC 20515

Dear Congressman Fuqua:

This letter is in response to your October 11, 1985 communication and attached questions regarding my testimony of October 3, 1985 before the Science Policy Task Force. My responses to your questions are detailed below.

1. One of the components of post-1980 R&D policy which you did not mention in your testimony is the attempt to stimulate joint venture research. What are the implications of your study with regard to joint venture research?

In many ways, the National R&D Policies which have recently been developed are directed toward stimulating joint venture research and in my opinion operate from a Schumpeterian hypothesis that oligopolistic type organizations are the optimum producers of research and development product. These policies do not recognize that the R&D laboratory of the various firms or organizations involved in joint venture activities are each a part of a distinct environmental setting.

This environmental setting does not necessarily have any correlation with the environmental setting of the parent organization. As a result, the laboratories actually conducting R&D as a part of the joint venture, exist within an environmental setting which is very different. Differences between these environmental settings results in great similarities in expectations and research direction of the various partners. These differences should be considered when designing R&D policies calling for joint research and development activities. In addition, it should be recognized that joint venture R&D activities may result in changing environments. For instance, an R&D laboratory that becomes involved in a joint venture activity that previously has not experienced much market influence could find itself moving toward a new environmental setting, and as a result experience changes that could affect not only the joint venture but the parent organization itself.

The main point here, is similar to the one made in my testimony, and that is that all R&D policies must contain some institutional thread. Institutions and their propensity to be

changed by the various policies that are suggested by the government should be considered when these policies are designed. In that regard, joint venture research policies should consider the fact that increasing the market influence on laboratory partners, who have previously not been influenced, could change how those organizations are likely to perform. One might consider special organizational arrangements to deal with the increased level of market influence that will be experienced by all organizations participating in joint venture research and activities.

2. How many public generic laboratories were rated in effectiveness out of your 32 laboratory sample, and how many of these were federal laboratories?

Of the 32 laboratories involved in the case study analysis, 5 were classified as public generic laboratories. These 5 were drawn from the 121 survey respondents who were classified as public generic laboratories. Of the public generic laboratories which participated in the case study phase of this study, one was an industrially owned and government financed research facility, three were government owned, contractor operated research facilities and one was a government owned, government operated research facility. It must be remembered that the government facilities, both government owned contractor operated and government owned government operated were also studied in the public multi market classification and the public market classification. The point is that all government laboratories are not public generic in their character. Of the 250 laboratories involved in the more general phase of the study, 41 were owned by the government, 46 were owned by an industrial concern, 140 were cooperatively owned by some combination of universities, government or industry, and 23 had mixed ownership status, that is they had portions of their facilities owned by one entitity and other portions owned by another entity. Each of these four laboratory types were dispersed throughout each of the new classification cells. There was a concentration of the government owned facilities in the three public laboratory types. The cooperatively and mixed owned laboratories also had a tendency to be classified public but there was a much greater distribution of these facilities among the new laboratory classification typology.

3. Of the federal laboratories rated in effectiveness, was there a significant variation in the effectiveness evaluation scores, and if so, how do you account for these variations?

Of the federally owned and operated laboratories and federally owned, contractor operated laboratories there was a significant variation in the effectiveness evaluation scores. Among the public generic laboratories, those laboratories which were federally owned and federally operated were slightly less effective than those laboratories which were federally owned and contractor operated. Among the federally owned and federally operated laboratories of the public generic

classification, the public multi-market classification and the public market classification, those laboratories which were federally owned and federally operated tended to have a lower level of effectiveness. It is, however, important to point out that this general tendency in effectiveness variation was for the most part a function of increase in market influence. It appears that among those federally owned federally operated research facilities which were also heavily influenced by the market we observed the lowest level of effectiveness. I believe that this was a result of the extremely difficult time that these laboratories had in managing their market influences as well as dealing with their role as government employees. Those laboratories which were federally owned and federally operated appeared to have an easier time in dealing with the market/government influence conflict problem, and in those areas where conflict was not as significant these laboratories also appeared to be more flexible. Again, the point here is that federal R&D laboratories did appear to be adversely affected by high levels of market influence, particularly when these laboratories were staffed by government employees.

4. Was there a significant variation in the effectiveness scores of the given agency laboratories, and if so, how do you account for these variations among a given agencies laboratories?

We did not conduct enough studies on laboratories within a single agencies sphere of influence to answer this question. We hope in the second phase of this study to deal with a much larger laboratory study population.

5. Of the federal laboratories rated in effectiveness, which were most effective, government owned, government operated or government, contractor operated laboratories? How do you account for the differences in effectiveness between these two types?

As I indicated in answer to question 3, in general the government owned, contractor operated laboratories were more effective. This was due to a number of variables, each of which is difficult to weight, but include the following: 1) lower levels of centralized agency control on scientific decision making, 2) lower levels of politicization in laboratory management activities, 3) a higher level of self determination in the research agenda setting process, 4) less involvement as a technical policy support group, 5) government owned, contractor operated laboratories were viewed as having particular contractor related strength or weaknesses that had developed over time, and as a result were viewed as semi-autonomous entities, 6) government owned contractor operated research facilities had substantially greater flexibility regarding personnel functions and organizational structure. There are, of course, other possible explanations, but in general these points summarize the major differences that we observed.

6. Of the federal laboratories rated in effectiveness, which were most effective, multi program laboratories or single purpose laboratories? How do you account for the differences in effectiveness between these two types?

The total number of multi-program and single program laboratories that were visited was not large enough to make any definite conclusions, but I do have some preliminary thoughts. In general, the multi-program laboratories were evaluated as being more effective in their ability to produce significant technical accomplishments and their general review by peers. Single program laboratories fared well within their own strategic constituency groups as well as in our own analysis of internal processes. What this means is that multi-program labs were deemed as being more effective for comprehensive scientific and technological activities and that the single purpose labs, while not viewed as being ineffective were less well known and therefore, seen as being less effective by many of our evaluators. Across the board, of all the facilities that we looked at those facilities which were larger in scope, with a number of program areas in general were observed as being more effective. The differences in effectiveness are linked again to the ability of the laboratories to work away from being extensively controlled by a single program within an agency or a single agency itself. The multi-program laboratories are institutions which put together their own research agendas and then to a large extent, these research agendas are supported by a number of different sources. From this type of funding pattern, these organizations are able to develop substantially greater flexibility as well as lower levels of bureaucratic control on their behavior, in the end possibly resulting in their lower levels of effectiveness.

I appreciated the opportunity to participate in the Task Forces' information gathering phase and would be happy to assist you in whatever way possible in any of your future tasks. Please don't hesitate to call on me in that regard.

Sincerely,

Michael M. Crow

PANEL: SCIENCE IN THE U.S. DEPARTMENT OF AGRICULTURE

Mr. FUQUA. We will now begin with our panel of witnesses who will discuss science in the Department of Agriculture. We have two witnesses from the Department of Agriculture, Dr. Terrence B. Kinney, Jr., the Administrator of the Agricultural Research Service, and an old flying buddy of mine, Dr. John Patrick Jordan, the Administrator of the Cooperative State Research Service, and our third panel member is Dr. Keith Huston, Cochairman of the National Agricultural Research Committee and Director-at-Large of the North Central State Agricultural Experiment Station Directors.

Dr. Kinney, we will begin with you. We will make all of your statements a part of the record. If you wish to summarize them, that will certainly be permitted, and then after you are all completed, then we'll go into a question and answer session.

STATEMENT OF DR. TERRENCE B. KINNEY, JR., ADMINISTRATOR, AGRICULTURAL RESEARCH SERVICE, U.S. DEPARTMENT OF AGRICULTURE, WASHINGTON, DC

Dr. KINNEY. Thank you, Mr. Chairman. I appreciate the opportunity to be here, and I will summarize my statement as concisely as possible.

I am Administrator of the Agricultural Research Service of the Department of Agriculture. To begin with, Mr. Chairman, I think it is important that I spend just a few minutes discussing what we perceive as and have in fact had published, that is, the mission of the Agricultural Research Service. That mission is to plan, develop, and implement research that is designed to produce the new knowledge and technologies required to assure the continuing vitality of the Nation's food and agricultural enterprise.

As a Federal research agency, we address problems of legitimate national concern, we conduct research that is appropriate for the Federal Government, and we exploit the unique capabilities of ARS scientists and the facilities that they operate. This is a combination that forms an integrated and coordinated national resource that is not duplicated by other research groups in the U.S. agricultural research and development system.

More specifically, ARS conducts research that is national in perspective, in that it focuses on significant problems affecting the entire Nation, or at least a significant geographic portion; research that is sufficiently long-range, high-risk, and of such broad scope as to require unified planning, continuity of effort, and a stable scientific environment that is maintained by Federal research laboratories; third, research that is not undertaken by other agricultural research institutions; fourthly, research that is uniquely a Federal responsibility, in that it is requested by Congress or the executive branch, it requires a structure ready to respond to emergency situations, in many cases it is international in nature, it supports the development and maintenance of important national collections, such as collections of seeds or insects, and so forth, and research that supports Federal action programs.

The research necessary to accomplish the goals inherent in our mission is conducted at about 140 locations throughout the United

States, and some of these locations are designed to address problems that are very specific in nature. Other facilities, such as our Beltsville facility which employs about 350 scientists, have a wide array of programs that are best addressed by a multidisciplinary approach, and they require equipment and facilities for many scientific disciplines and activities. The ARS facilities are located throughout the United States and in eight locations overseas.

Obviously this tremendous research effort requires constant, comprehensive monitoring, so that shifts of emphasis, redirections of programs, and additional research focus can be done in an orderly and timely fashion. Toward this end, we recently developed the ARS program plan which outlines research possibilities for the next 20 to 50 years, along with a companion document, a 6-year implementation plan that identifies research areas for increased or decreased emphasis in the next 1 to 6 years, and this program is updated at least once every 2 years.

Mr. Chairman, priority-setting is complex and is dynamic. It's an interactive process among staff and line scientists, and includes considerations of both the scientific community and research users. Decisions by the Secretary of Agriculture, the Office of Management and Budget, the Congress and others, determine the ARS appropriation and can affect the allocation of funds to specific locations and areas of research.

However, within ARS, individual scientists, along with our area directors and their staffs, significantly influence priorities based on their analyses of the needs for equipment, facilities, and for personnel for exploiting scientific opportunities. Outside of the ARS, there are many groups, such as the Joint Council, the Users Advisory Board, and many other Federal environmental and other Federal agencies that impact on our planning and priority-setting process.

For the setting of priorities I rely on the Deputy Administrator and the national program staff to plan, to articulate and evaluate the national ARS programs. The national program staff, working with our line organization and all other groups that interact with us, identifies research opportunities that are conducted by other organizations and research needs that are expressed by all of the groups I identified earlier, and those recommendations are identified throughout the year in action memoranda, in option papers, budget analyses, budget preparation, summaries of program reviews, and many, many other documents.

The criteria for setting priorities and allocating resources are outlined in the complete statement, and I won't go through those now. Several factors may constrain the allocation of resources and the kinds of research that ARS conducts, and limit in many ways the flexibility in resource use.

The following factors, which include major constraints, must be considered continually by ARS: one is the availability of scientific expertise; another, the limitations of geography, climate, and soil. Very often research must be conducted in a number of different geophysical locations in order to have meaning. The nature of the problem obviously is important, because sometimes very costly facilities or equipment or special scientific expertise are required. The sequential nature of research is important to consider in priority setting. Sometimes we can't do one piece of research until we

have completed some other. And then the continuous adaptation of biological systems is important and creates new research problems as we solve one—that is, through the development of resistance of plants and animals and so forth.

No totally objective formula is possible for setting priorities and allocating resources for research. Priority setting for research is the exercise of informed judgment. It is based on pertinent criteria and given constraints. At the project level, scientific criteria and experience will predominate. At the national level, scientific criteria must be balanced with Federal policies and with the needs of action agencies and other users of research who are represented at the national level.

Part of achieving that balance and providing the environment for creative research is assuring our scientists the use of the new tools of the trade. Several new technologies are emerging from recent research in the biosciences, particularly advances in molecular biology in the 1960's, and ARS fully supports the use and development of these new technologies to help find solutions to some of the vexing and intractable problems that have faced U.S. agriculture. Called biotechnology, this still-growing field now offers unprecedented opportunities to study and understand the fundamental life processes precisely. Many universities and industrial organizations treat biotechnology as a separate priority. However, ARS chooses to use biotechnology research throughout much of its total program as part of its arsenal of tools in fulfilling its specific mission and program goals. ARS does not concentrate its biotechnology research at specific centers, nor does it plan to do so. In fact, the 5 percent of the ARS fiscal year 1985 funding specifically devoted to biotechnology research is distributed among 200 scientists at 41 different locations. The ongoing biotechnology research is directed toward the solution of high priority agricultural problems of national scope. These include things like conserving and maintaining the quality of natural resources, reducing high costs of farm production, improving crop protection and production efficiency, and so forth.

ARS formally reviews each research project at least once every 3 years, and I will simply complete this by saying that the review process is very complex and involves the best scientific expertise available. It's an ongoing process, and the 3 years is at least at a minimum. Many of our projects are reviewed each year, some of them on a 3- to 6-month basis.

Proposed new research projects compete for available program funds. Each proposed new project is reviewed by peer scientists from the agricultural science community to determine whether or not it should be implemented, regardless of what the funds are earmarked for. One very effective method of reviewing research focuses on the scientist who carries it out, and I simply want to say here that the Agricultural Research Service has the most sophisticated research grade evaluation system of any organization in the country, in my opinion. It is one of the few Federal agencies that has a peer review process for evaluating our scientists, and this is probably the most effective means of determining whether or not research is good, bad, indifferent, or should be continued.

The Agricultural Research Service strongly supports the separate personnel system for scientific and technical personnel proposed by the Federal Coordinating Council for Science, Engineering, and Technology—the committee known as FCCSET—that would change legal and regulatory barriers inhibiting our hiring and retaining scientific stars and superstars. If we are going to retain the best scientists, we have got to be able to reward them.

The use of postdoctoral fellows is another excellent mechanism that ARS uses to bring new ideas, capabilities, and techniques to ARS research, and we aggressively pursue these advantages. The Agricultural Research Service's research associate program, funded from the Administrator's office, has grown from 25 positions in 1984 to 50 in 1985, and we have approved the funding of 100 of these in 1986. There are at present some 250 other postdoctoral scientists throughout ARS. In addition, ARS has a fellowship program which provides opportunities for our research scientists and our administrative personnel to participate in programs up to one year in research or education at an accredited domestic or foreign educational institution or research facility.

Those new ideas and capabilities continue to be necessary to ARS as we maintain our emphasis on mission-oriented fundamental, long-range, high-risk research to solve specific problems. For several decades, as you know, the generation of fundamental agricultural knowledge—the seed corn, if you will, of technology—has not kept pace with its exploitation into useful technology. That knowledge has been used to solve relatively tractable problems at the expense of generating the new knowledge needed to solve resistant problems. Helping to fill the knowledge gap is clearly a Federal research responsibility, particularly in those rapidly advancing areas that offer potential for increasing agricultural productivity.

Finally, gentlemen, the mission, the planning, the priorities would mean little unless research results reach those who need and use them. We not only work very closely with other agencies of the USDA and the Federal establishment but also with the private sector. Last year we had more than 60,000 contacts with business and industry to transfer our technology to the private sector. These are one-on-one contacts between our scientists and industry. Many of these contacts were face-to-face discussions. The national program staff met with no fewer than 150 industry and commodity groups, and I participated in 30 of these sit-down sessions where we, eyeball-to-eyeball, talked about research and research priorities. These discussions and contacts help to keep our 2,650 scientists operating in the real world, and we expect to continue them.

For the reference of the task force, Mr. Chairman, I have several documents—our mission statement, our program plan, and so forth—that will be made available to members of the committee, and I will be pleased to respond at the appropriate time to any questions. Thank you.

[The prepared statement of Dr. Kinney follows:]

STATEMENT OF

DR. TERRY B. KINNEY, JR.

ADMINISTRATOR

AGRICULTURAL RESEARCH SERVICE

U. S. DEPARTMENT OF AGRICULTURE

BEFORE THE

TASK FORCE ON SCIENCE POLICY

OF THE

COMMITTEE ON SCIENCE AND TECHNOLOGY

U. S. HOUSE OF REPRESENTATIVES

OCTOBER 3, 1985

Mr. Chairman, I am Terry Kinney, Administrator of the Agricultural Research Service (ARS) of the Department of Agriculture and I appreciate the opportunity to be here today to discuss with the Task Force the issue of the current and future role of our Federal laboratories in the conduct of research to continue and to further enhance this Nation's agricultural well-being.

To begin, Mr. Chairman, I think it is important that I spend a few minutes discussing what we perceive as--and have, in fact, had published--the mission of ARS. That mission is to plan, develop, and implement research that is designed to produce the new knowledge and technologies required to assure the continuing vitality of the Nation's food and agriculture enterprise. As a Federal research agency, ARS (1) addresses problems that are of legitimate national concern, (2) conducts research that is appropriate for the Federal Government, and (3) exploits the unique capabilities of ARS scientists and the facilities they operate--a combination that forms an integrated and coordinated national resource that is not duplicated by others in the full U.S. agricultural research and development system. Each ARS laboratory has a defined mission which is consistent with its appropriate role within ARS and the R&D community as a whole.

More specifically, ARS conducts research that is--

1. National in perspective in that it focuses on significant problems affecting the entire Nation or its several broad geographic areas;

2. Sufficiently long range, high risk, and of such broad scope as to require the unified planning, continuity of effort, and stable scientific environment maintained by the Federal research organization;

3. Not undertaken by other agricultural research institutions because of their narrower geographic focus or shorter term perspective; and

4. Uniquely a Federal responsibility in that it--

   a. Is requested by Congress or the Executive Branch and requires special skills, facilities, or capabilities of ARS;

   b. Requires a structure ready to respond to emergency situations of regional or national significance;

   c. Is international in nature, supporting foreign policy initiatives of the U.S. Government;

   d. Supports the development and maintenance of important national collections that are essential to scientific activities; or

   e. Supports Federal action programs.

The research necessary to accomplish the goals inherent in our mission is conducted in 140 locations. Most ARS facilities are owned and operated by ARS, but several locations are provided by the U.S. General Services Administration or are leased. Some locations are designed to address research problems that have a very specific focus. Other facilities such as the large 350-scientist facility at the Beltsville (Maryland) Agricultural Research Center (BARC) have a wide array of programs that are best addressed by a multidisciplinary approach and require equipment and facilities for many scientific disciplines and activities. ARS facilities are located throughout the United States and overseas so that problems of regional, national, and international nature can be addressed under the most favorable research environment. Many are located on university campuses and State agricultural experiment stations because of a unique opportunity for cooperation and interaction with State scientists.

This tremendous research effort requires constant comprehensive monitoring so that shifts of emphasis, redirections of programs and additional research focus can be done in an orderly and timely fashion. Toward this end, ARS recently developed a Program Plan which outlines research possibilities for the next 20 to 50 years and a 6-Year Implementation Plan which identifies research areas for increased or decreased emphasis depending on the current research needs. ARS continues to seek ways to improve the efficient use of its facilities and will give increasing emphasis to the optimum use of facilities and resources as redirections prescribed in the 6-Year Implementation Plan are carried out.

INTENTIONAL BLANK

Priority setting is complex and dynamic. It is an interactive process among staff and line scientists and includes considerations of both the scientific community and research users. Decisions by the Secretary of Agriculture, Office of Management and Budget, and the Congress determine the ARS appropriation and can affect the allocation of funds to specific locations and areas of research. Within ARS, individual scientists, along with Area Directors and their staffs, significantly influence priorities based on their analyses of needs of equipment, facilities, and personnel for exploiting scientific opportunities. Outside of ARS, the Joint Council on Food and Agricultural Sciences, the Users Advisory Board, leaders of farm organizations, industrial groups, and professional societies can influence priorities. The USDA action and regulatory agencies that depend upon ARS for research--agencies such as the Animal and Plant Health Inspection Service, Soil Conservation Service, Food and Nutrition Service, Food Safety and Inspection Service, Agricultural Marketing Service, Federal Grain Inspection Service, and Foreign Agricultural Service--can also influence priorities. At times, the research needs of agencies such as the Environmental Protection Agency, Agency for International Development, Department of Defense, National Aeronautics and Space Administration, Extension Service, Forest Service, and Bureau of Land Management will enter the process. Analyses and projections by the Economic Research Service, other agencies, and organizations also will be considered.

For the setting of priorities, the Administrator's office relies on the Deputy Administrator and the National Program Staff (NPS) to plan, articulate, and evaluate national ARS programs. The NPS identifies research opportunities, research that is conducted by other organizations, and research needs that are expressed by user and advisory groups. The NPS develops recommendations for program redirections and budget requests. Those recommendations will be included in action memoranda, option papers, budget analyses, summaries of program reviews and evaluations, or other appropriate documents.

The main criteria for setting priorities and allocating resources are:

- Consistency with the objectives and goals of the Congress, the Department, and the Agency;

- Need for research to solve specific high priority national technical problems determined to be critical to the U.S. food and agriculture sector;

- Need for the research as expressed by ARS scientists, user groups, Federal agencies, and the general scientific community;

- Potential benefits expected from achieving the stated objectives;

- Research capabilities and capacity of the scientists, laboratory, or program;

- Probability of success;

- Amount and kind of research effort conducted by other research organizations.

Several factors may constrain the allocation of resources and kinds of research that ARS conducts and limit the flexibility in resource use. The following factors, which include major constraints, must be considered:

- Availability of scientific expertise. Successful research depends upon the training and experience of individual scientists and upon the teamwork within and among laboratories. For both individuals and research teams, many years are required to reach peak productivity.

- Limitations of geography, climate, and soil. For valid results, certain types of research, especially field research, must be conducted at problem sites and over extended periods.

- Nature of the problem. Much ARS research requires costly facilities and equipment that are problem-specific. Quarantine facilities and special equipment for work on recombinant DNA and foreign animal diseases are examples.

- Sequential nature of research. Often, one phase of research must be completed before the next phase can be started.

- Continuous adaptation of biological systems. Examples are the resistance of crop pests to chemical controls and the genetic improvement of crops that may introduce new vulnerabilities. Goals and priorities must be revised to meet new problems as they arise.

No totally objective formula is possible for setting priorities and allocating resources for research. Priority setting for research is the exercise of informed judgment. It is based on the criteria and constraints listed above; all the factors are important at some level of decision making. At the project level, scientific criteria and experience will predominate. At the national level, scientific criteria must be balanced with Federal policies and with the needs of action agencies and other users of research. It is the task of the Administrator, Deputy Administrator, and the NPS to achieve such a balance so that ARS may provide its scientists with the long-term stability and the firm commitments that are needed for creative research.

Part of achieving that balance and providing the environment for that creative research is assuring our scientists the use of the new "tools of the trade". Several new technologies are emerging from recent research in the biosciences, particularly the advances in molecular biology of the 1960's. ARS supports use and development of these new technologies to help find solutions for some of the most vexing and intractable problems facing U.S. agriculture.

Called biotechnology, this still-growing field now offers unprecedented opportunities to study and understand fundamental life processes precisely. Application of this knowledge can be used to solve problems, produce new products, and provide other economic and social benefits.

Many universities and industrial organizations treat biotechnology as a separate priority. However, ARS chooses to use biotechnology research throughout much of its total program as part of its arsenal of tools in fulfilling its specific missions and program goals. ARS does not concentrate its biotechnology research at specific centers, nor does it plan to do so. In fact, the 5 percent of the ARS fiscal year 1985 funding specifically devoted to biotechnology research is distributed among 200 scientists at 41 locations.

ARS' ongoing biotechnology research is directed toward the solution of high-priority agricultural problems of national scope. These include conserving and maintaining the quality of natural resources; reducing high costs of farm production, improving crop protection and production efficiency, and enhancing market value and quality of farm products; overcoming technical

barriers to marketing and export of agricultural products; and promoting human health and well-being through nutrition.

ARS formally reviews each research project at least once every three years. Program reviews are organized to determine whether current and projected research programs are consistent with the mission and established priorities of the agency. These reviews also assess progress and productivity of the scientists and determine the effectiveness of team research. Consideration is given to personnel assignments, allocation of resources and facilities, need for program changes, and ways to strengthen research. Review panels include research leaders and scientists from the laboratories under review and scientists from other Government agencies, the academic community, and industry.

Proposed new research projects compete for available program funds. Each proposed new project is reviewed by peer scientists from the agricultural science community to determine if it should be implemented.

One very effective method of reviewing research focuses on the scientist who carries it out. Application of the Research Grade-Evaluation Guide, grade levels for scientific positions are determined by committees (often referred to as peer panels) rather than by a single classification specialist--the usual practice in the Federal Government. Scientists prepare written material describing their research and an appropriate panel periodically reviews the position. Panels consist of a committee chairperson (usually a research manager), an executive secretary (a classification specialist), and five scientists.

ARS strongly supports the separate personnel system for scientific and technical personnel proposed by the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET) that would change legal and regulatory barriers inhibiting our hiring and retaining scientific stars and superstars. In the meantime, we are exercising special care to be very selective in our initial selection procedures. This includes increasing use of search committees as appropriate to identify exceptionally promising new scientists to fill research vacancies at our major centers.

The use of postdoctoral fellows is an other excellent mechanism to bring new ideas, capabilities, and techniques to ARS research, and we are aggressively pursuing these advantages. The ARS research associateship program funded from the Administrator's office has grown from 25 positions in 1984 to 50 in 1985 and 100 will be funded in 1986. There are at present some 250 other postdoctoral scientists throughout ARS. In addition, ARS has a Fellowship Program which provides opportunities to research scientists and administrative personnel to participate in a one-year research or education program at an accredited domestic or foreign educational institution or research facility of their choice.

Those new ideas and capabilities continue to be necessary to ARS as we maintain our emphasis on mission-oriented, fundamental, long-range, high-risk research to solve specific problems. For several decades, the generation of fundamental agriculture knowledge, the "seed corn" of technology, has not kept pace with its exploitation into useful technology. That knowledge has been used to solve

relatively tractable problems at the expense of generating the new knowledge needed to solve resistant problems. Helping to fill the knowledge gap is clearly a Federal research responsibility, particularly in those rapidly advancing areas that offer potential for increasing agricultural productivity. In the judgment of ARS managers, mission-oriented, fundamental research should account for about 50 percent of the ARS program between 1984 and 1990. Historical and current data for the ARS investment in fundamental research and analysis of the changes in program emphasis projected for the six years indicate that the investment in fundamental research will not vary from 50 percent by more than plus or minus 10 percent. Whether we classify our research as fundamental or applied it is always problem-solving research.

Finally, Gentlemen, the mission, the planning, the priorities would mean little unless research results reached those who need and use them. We not only work very closely with other agencies of USDA but also with the private sector. Last year we had more than 60,000 contacts with business and industry to transfer our technology to the private sector. Many of these contacts were face-to-face discussions. The National Program Staff met with no fewer than 150 industry and commodity groups, and I was able to participate in 30 of these meetings. Such discussions and contacts help keep our 2,650 scientists operating in the "real world" of commerce and agriculture. In addition, the agency published its formal technology transfer program in 1984.

For the reference of the Task Force I have a few copies of the publications I've referred to--they may be of interest. This concludes my prepared statement, Mr. Chairman, I will be pleased to respond to any questions you may have.

Mr. FUQUA. Thank you very much, Dr. Kinney.
Dr. Jordan.

STATEMENT OF DR. JOHN PATRICK JORDAN, ADMINISTRATOR, COOPERATIVE STATE RESEARCH SERVICE, U.S. DEPARTMENT OF AGRICULTURE, WASHINGTON, DC

Dr. JORDAN. Mr. Chairman and members of the task force, thank you very much for the opportunity to come before you. I hope as a result of my presentation, the close working relationship between the Cooperative State Research Service, for which I am the Administrator, and the Agricultural Research Service, for which Dr. Kinney is the Administrator, will come through.

CSRS, as we are known, is the science and education agency through which Federal research funding and planning is accomplished on behalf of the U.S. Department of Agriculture in cooperation with 58 State and Territorial Agricultural Experiment Stations, 17 historically black land-grant institutions, including Tuskegee University, 28 schools of forestry, and 29 colleges of veterinary medicine. Most of these institutions are part of the land-grant university system.

When you total all the publicly supported agricultural research, including the research agencies of the U.S. Department of Agriculture, two-thirds of all the full-time equivalent scientists are found in the State Agricultural Experiment Station system. Because of the shared responsibilities between research and teaching and also between research and extension, the actual number of scientists involved is 12,500, who supervise 13,000 graduate students and 7,200 technicians. This, Mr. Chairman, provides a wide range of talent capable of addressing most kinds of problems faced by agriculture.

The funding of the total system of State Agricultural Experiment Stations and associated institutions is also relatively unique. The total amount of money available in that system last year totalled nearly $1.3 billion, but it comes from several sources—53 percent of it from State appropriations; 19 percent of it through the budget of the Cooperative State Research Service; another 10 percent from industrial organizations; 9 percent from other Federal agencies, particularly the National Science Foundation and the National Institutes of Health. Six percent of it comes from the sale of the residue of research, the sales of those products that are safe, and finally 3 percent from other USDA agencies, particularly the Agricultural Research Service and the Economic Research Service.

Mr. Chairman, I would like to specifically address the role of my agency in the science and engineering infrastructure and to outline our priority-setting process. The most significant thing I can say to you is that the program planning and priority setting is done in close cooperation with the State Agricultural Experiment Station system, and it is done on a systemwide basis, with CSRS providing a catalytic role that involves planning, priority-setting, and validation of the quality of research, and an evaluation of accomplishments.

The history of the current system dates back to the late 1960's, when the land-grant system began a 5-year cycle of planning, updated every 2 years. The system has moved recently to a more

structured strategic planning mode and in fact this year, Mr. Chairman, a national symposium followed by a workshop established the highest priorities on a national basis for the entire system.

Such strategic planning is translated into station-level planning and specific program-level planning for each fiscal year in the CSRS budget, and you'll see shortly from Dr. Huston how that is translated at the individual Station level. There are frequent tradeoffs that are seen at the Station level.

To give you an example, for nearly a dozen years I was director of the Colorado Agricultural Experiment Station, and that State ranks No. 1 in lands in feedlots. Nevertheless, that Station went out of the sheep research business. How was it able to do this? It was able to accomplish this by close coordination and cooperation with other agencies and States. To begin with, the USDA through the Agricultural Research Service has an excellent program in sheep research at Dubois, ID. Utah State University had a well coordinated and developed program at Logan, UT, and the University of Wyoming also has a significant research program in sheep. Our role at Colorado was to employ a very effective extension specialist to gather the information provided from these resources and package it in a form that could be used by the sheep producers of Colorado.

The tradeoff was that Colorado State University was able to focus its attention much more heavily on the reproduction of beef, a problem of highest priority in the State, and to put a lot more resources behind that. As a result of that effort, the institution provided leadership on a national basis, really, in superovulation, cloning of livestock, animal gene manipulation, and other technologies. Similar stories can be found and articulated for a number of other Stations as well.

At the heart of this effort is the assurance of quality of science, and that covers the entire span of research from the evaluation of a research concept to the accomplishment of research objectives. The basic mechanism through which assurance of quality of science is accomplished is the review by panels of scientists, highly competent in each scientific problem area. This is accomplished in about five ways: first of all, a system of Station-level peer reviews of individual project proposals; second, nationally organized panels of peers, particularly to address the Special Research Grants and always in the Competitive Research Grants program; third, active participation in regional research projects, which involves a coordinated effort of several States, along with appropriate Federal agencies, focusing on common problems; and a system of regular program reviews conducted at each research site with, again, a panel of peer experts; along with an annual review of each and every project at the Station level.

In the case of regional research, the project under development is critically reviewed by a research committee of the Regional Association of Experiment Station Directors. Following the recommendation of the regional research committee, the project is forwarded to CSRS only if it meets the approval criteria of the directors association. Upon receipt of a regional research project, CSRS arranges for its critical review by the committee of nine which has been es-

tablished by the Secretary of Agriculture for such purposes. The committee of nine, in the development of their review process, have at their disposal the entire scientific community as advisers and consultants. Thus, each project is provided ample opportunity for critical analysis and modification for possible improvement.

Mr. Chairman, you asked that I speak specifically about the mechanisms used to fund research programs within CSRS and the long-term trends in terms of program and mechanism. We use basically three mechanisms: Competitive Research Grants, Special Research Grants, and base program funding. If I may, I would like to discuss the size and scope, the assurance of quality, the strengths and weaknesses of each of these mechanisms. I hope this discussion will illustrate the distinct strengths of each mechanism and each approach. I also hope that I will now be able to show you that, when fitted together, these mechanisms do work well and each mechanism has their own niche to fill.

In fiscal year 1985 CSRS, through its Office of Grants and Program Systems, managed $54 million worth of Competitive Grants. These were in areas including biotechnology, plant sciences, animal sciences, pest sciences, human nutrition, and forestry. The Competitive Grants program is organized and managed in a manner quite analogous to the National Science Foundation. It is based on panels of peers that meet in Washington, DC, for the purpose of reviewing all proposals that are submitted in response to a published call for proposals, by scientists in universities, Federal laboratories, and in industry.

The average panel consists of about 14 scientists and generally reviews about 140 proposals, ranking them in the order of priority. The strength of this system is that it opens competition to the very best talent, regardless of whether it be public or private, Federal or State, industry or academic in its foundation. This program provides national focus and emphasizes innovative ideas and specific areas of research to be addressed. The major weaknesses of this system are the length of time and the cost involved in preparing proposals which generally are funded for relatively short periods of time—in CSRS, generally 2 years at a time. All decisions are made on a central basis nationally, and therefore it brings national focus as opposed to another mechanism which we'll talk about, which brings particularly State and local focus to it.

In fiscal year 1985, CSRS administered $32 million in the Special Research Grants category, which are targeted to specific problem areas and sometimes to specific locations. There were a total of 40 programs, each proposal of which was peer review. The strengths of this approach are that it brings definite focus to a problem area, gives it visibility, and provides funding for programs with a limited life span, generally in the range of 5 years, and it allows both the administration and the Congress to respond in a rather short timeframe to new needs. However, by identifying a specific site to conduct research, the quality of science may not be the highest and the research objective might be better served if a wider range of institutions and locations could be considered. Most of the Special Grants are in that category, where the site is not all that specified. Additionally, Special Research Grants invite a selection of specific projects by legislative action which, again, might not have the

same scientific credibility or standards as those required in the Competitive Research Grants program..

By far the largest mechanism that CSRS is involved in is the base or formula-funded program. In fiscal year 1985 it involved every aspect of agricultural research, including basic and applied research; plant, animal, and microbial oriented research; marketing and international trade; world communities and the people who live therein; as well as human nutrition and the use of agricultural products. The three major programs under this heading are the Hatch Program, which involves all the State Agricultural Experiment Stations, the colleges of home economics, the colleges of veterinary medicine, schools of forestry in the land-grant institutions, and amounts to $162.2 million. The Evans-Allen Program is for colleges eligible under the second Morrill Act and Tuskegee University, and amounts to $23.5 million. Finally, the McIntire-Stennis Program, which is available to 62 schools and departments of forestry, both in the land-grant universities and selected non-land-grant universities, and amounts to $13.1 million. On average, a dollar of this shared funded program—all of these three—leverages in more than $4 of funding from other sources.

The strong point in favor of this program is that it is conducted at the State level with State input and is overseen by the State legislature. Management is provided through the State land-grant university or other eligible institution. It inevitably involves and holds accountable the university president, the Experiment Station director, the dean and department heads, as well as individual scientists funded through this mechanism. It allows response to the highest priority needs of each State or territory. Its major weakness may be the question of whether the best talent to address a particular question is present in a given institution.

The basic mechanism for assuring the quality of research in this kind of program is the Station-level peer review system, and that in each and every case has been submitted to CSRS for approval and is on file in my office. CSRS, together with the land-grant university system, is currently examining the impact and quality of the review process itself. This is being done in full cooperation with the participating institutions.

Let me turn my attention, Mr. Chairman, if I might, to the issue of scientific expertise. CSRS, through the Office of Grants and Program Systems, houses the higher education program for the Department of Agriculture. This involves strengthening grants to the colleges of 1890 and Tuskegee University and the Morrill-Nelson Act, which is also targeted to the land-grant institutions. In addition, there is a training grant program supporting 300 predoctoral students.

These awards are made on the basis of national competition from proposals submitted by participating institutions. A panel of peers is used to select the winning institutions and proposals. This program, combined with the other sources of funding, supports masters level, Ph.D. level, and post-doctoral level students and provides the major mechanism through which the scientific talent to meet America's future needs in agricultural research, extension, and teaching. Let's remember, Mr. Chairman, that essentially all of the agricultural scientists of the United States, including virtually all

of those in the Federal research laboratories, are products of that educational system.

The major mechanisms for interfacing will be discussed at length tomorrow when Assistant Secretary Orville G. Bentley comes before this body. Let me share with you a flavor of what he will say, simply by indicating that the Joint Council on Food and Agricultural Sciences—a congressionally-mandated organization—is the place at which the Agricultural Research Services, the Economic Research Service, forestry research, the land-grant institutions, the non-land-grant institutions, teaching, research, and extension all meet on common ground for common planning and common execution of programs.

The payoff for this kind of effort is substantial for the United States. With respect to the Experiment Stations, we see with less than 20 percent of the funding coming from the Federal Government, the Nation shares the benefits for an overall agricultural research system involving all the State Agricultural Experiment Stations, and the system is well-coordinated with the Agricultural Research Services, the ERS, the U.S. Forest Service, and other relevant Federal research agencies. In fact, Mr. Chairman, there is daily contact between my office and the National Science Foundation and the National Institutes of Health, as to particular examples, as well as U.S. AID in the State Department.

Second, there are significant tradeoffs, as previously indicated, where one agency or Experiment Station may take an in-depth approach on a particular research question, sharing the results with other Stations and the Federal Government. Farmers and ranchers benefit from this in terms of cutting input costs, and the citizen benefits through the availability of high quality food, fiber, fuel, and forest products, but the baseline of this is, the major focus is in cutting input costs so that American agriculture can be competitive on a worldwide basis.

I would like to summarize by saying that CSRS uses three main forms of funding, all of which are built on the basis of review of the quality of science and thus the assurance of the quality of science by means of peer panels. Each funding mechanism has a different function. The base funding program provides a foundation upon which the other two, the Special and Competitive Grants programs, are built, and builds also a strong basis on which funding from other Federal agencies, the State agencies and the State legislatures, as well as industry, can be built within those institutions, those universities. Its priorities are set by the scientific community and carefully synchronized with those of the Joint Council on Food and Agricultural Sciences. The system fits neatly together, with complementarity in programs and in output to Federal laboratories. It is an ideal example of the New Federalism, where decentralized management and assurance of quality of science are at the heart of the system. No nation, sir—no nation—has ever built such a knowledge-based system with such high quality science at such a low relative Federal cost as we have. The Congress and the people of the United States, sir, are to be congratulated.

I would be pleased to answer questions.

[The prepared statement of Dr. Jordan follows:]

STATEMENT OF

DR. JOHN PATRICK JORDAN

ADMINISTRATOR

COOPERATIVE STATE RESEARCH SERVICE

U.S. DEPARTMENT OF AGRICULTURE

BEFORE THE

TASK FORCE ON SCIENCE POLICY

OF THE

COMMITTEE ON SCIENCE AND TECHNOLOGY

U.S. HOUSE OF REPRESENTATIVES

OCTOBER 3, 1985

COOPERATIVE STATE RESEARCH SERVICE

Mr. Chairman and Members of the Task Force: I am Dr. John Patrick Jordan, Administrator of the Cooperative State Research Service (CSRS). CSRS is the science and education agency through which federal research funding and planning are accomplished on behalf of the Department of Agriculture in cooperation with:

- 58 State and Territorial Agricultural Experiment Stations
- 17 Historically Black Land-Grant institutions, including Tuskegee University
- 28 Schools of Forestry, and
- 29 Colleges of Veterinary Medicine

Most of these institutions are a part of the Land-Grant university system. When you total all the publicly supported agricultural research, including all research agencies within the United States Department of Agriculture, two-thirds of all the full-time equivalent scientist years are found in the State Agricultural Experiment Station system. Because of shared responsibilities between research and teaching in the universities, the actual number of scientists involved is 12,500 who supervise 13,000 graduate students and 7,200 technicians. This provides a wide range of talent capable of addressing most kinds of problems faced by agriculture.

THE FUNDING LEVEL FOR THE TOTAL SYSTEM OF STATE AGRICULTURAL EXPERIMENT STATIONS AND ASSOCIATED INSTITUTIONS AMOUNTS TO NEARLY $1.3 BILLION PER YEAR. IT COMES FROM SEVERAL SOURCES. THE MOST RECENT DATA SHOW THE FOLLOWING SOURCES OF FUNDS:

o STATE APPROPRIATIONS	- 53%	o OTHER FEDERAL	- 9%
o CSRS APPROPRIATION	- 19%	o PRODUCT SALES	- 6%
o INDUSTRIAL ORGANIZATION	- 10%	o OTHER USDA	- 3%

EACH SOURCE OF FUNDING FILLS A SPECIFIC NICHE, BUT THE BASE FUNDING FOR THE ENTIRE SYSTEM COMES FROM THE COMBINATION OF STATE APPROPRIATED FUNDS AND FEDERAL FORMULA FUNDING THROUGH CSRS. PEAKS OF EXCELLENCE AND FOCUSED SCIENTIFIC EFFORT ARE PROVIDED THROUGH SOURCES OF FUNDING BEYOND THE BASE FUNDED PROGRAM.

INFRASTRUCTURE AND PRIORITY SETTING

IN ADDITION, MR. CHAIRMAN, I WOULD LIKE TO SPECIFICALLY ADDRESS THE ROLE OF MISSION AGENCIES IN THE SCIENCE AND ENGINEERING INFRASTRUCTURE AND TO OUTLINE OUR PRIORITY SETTING PROCESS. THE MOST SIGNIFICANT THING I CAN TELL YOU, IS THAT PROGRAM PLANNING AND PRIORITY SETTING IS DONE ON A SYSTEM-WIDE BASIS, WITH CSRS PROVIDING A CATALYTIC ROLE THAT INVOLVES PLANNING, PRIORITY SETTING, AND VALIDATION OF THE QUALITY OF RESEARCH, AND EVALUATION OF THE ACCOMPLISHMENTS.

THE HISTORY OF THE CURRENT SYSTEM DATES FROM THE LATE 1960'S, WHEN THE LAND-GRANT SYSTEM BEGAN PLANNING IN FIVE-YEAR CYCLES WITH UPDATES MADE EVERY TWO YEARS. THE SYSTEM HAS MOVED, MORE RECENTLY, TO A STRUCTURED STRATEGIC PLANNING MODE, AND IN FACT, THIS YEAR A NATIONAL SYMPOSIUM FOLLOWED BY A WORKSHOP ESTABLISHED THE HIGHEST PRIORITIES ON A NATIONAL BASIS FROM THE ENTIRE SYSTEM. SUCH STRATEGIC PLANNING IS TRANSLATED INTO STATION LEVEL PLANNING AND SPECIFIC PROGRAM LEVEL PLANNING FOR EACH FISCAL YEAR IN THE CSRS BUDGET. THERE ARE FREQUENT TRADE-OFFS AT THE STATION LEVEL.

TO GIVE YOU AN EXAMPLE, I WAS FOR NEARLY A DOZEN YEARS THE DIRECTOR OF THE COLORADO AGRICULTURAL EXPERIMENT STATION. THAT STATE RANKS AS NUMBER ONE IN THE NATION IN LAMBS IN FEED LOTS. NEVERTHELESS, OUR STATION WENT OUT OF THE SHEEP RESEARCH BUSINESS. HOW WERE WE ABLE TO DO THAT? WE WERE ABLE TO ACCOMPLISH IT BECAUSE THE USDA THROUGH ARS HAD AN EXCELLENT PROGRAM IN SHEEP RESEARCH AT DUBOIS, IDAHO; UTAH STATE UNIVERSITY HAD A WELL COORDINATED AND RELATED PROGRAM AT LOGAN, UTAH AND THE UNIVERSITY OF WYOMING ALSO HAD SOME RESEARCH IN SHEEP. OUR ROLE IN COLORADO, WAS TO HAVE A VERY COMPETENT EXTENSION SPECIALIST GATHER THE INFORMATION PROVIDED FROM THESE SOURCES AND PACKAGE IT FOR USE BY THE SHEEP PRODUCERS OF COLORADO. THE TRADE-OFF WAS THAT COLORADO STATE UNIVERSITY WAS ABLE TO FOCUS ITS ATTENTION MUCH MORE HEAVILY ON REPRODUCTION IN BEEF, A PROBLEM OF HIGHEST PRIORITY TO THE STATE. AS A RESULT OF THAT EFFORT, CSU PROVIDED LEADERSHIP IN SUPEROVULATION, CLONING OF LIVESTOCK, AND ANIMAL GENE MANIPULATION. SIMILAR STORIES ARE FOUND IN A NUMBER OF OTHER STATIONS.

ASSURANCE OF THE QUALITY OF SCIENCE COVERS THE ENTIRE SPAN OF RESEARCH FROM THE EVALUATION OF A RESEARCH CONCEPT TO THE ACCOMPLISHMENT OF THE RESEARCH OBJECTIVES. THE BASIC MECHANISM THROUGH WHICH THE ASSURANCE OF QUALITY OF SCIENCE IS ACCOMPLISHED IS THE REVIEW BY PANELS OF SCIENTISTS HIGHLY COMPETENT IN EACH SCIENTIFIC PROBLEM AREA. THIS IS ACCOMPLISHED THROUGH: (A) A SYSTEM OF STATION LEVEL PEER REVIEWS OF INDIVIDUAL PROJECT PROPOSALS; (B) NATIONALLY ORGANIZED PANELS OF PEERS, PARTICULARLY IN THE SPECIAL GRANTS AND ALWAYS IN THE COMPETITIVE GRANTS PROGRAM; (C) ACTIVE PARTICIPATION IN REGIONAL RESEARCH PROJECTS WHICH INVOLVE A COORDINATED EFFORT OF SEVERAL STATES, ALONG WITH APPROPRIATE FEDERAL AGENCIES FOCUSED ON A COMMON PROBLEM; AND (D) A SYSTEM OF REGULAR PROGRAM REVIEWS CONDUCTED AT EACH RESEARCH SITE WITH, AGAIN, A PANEL OF PEER EXPERTS; ALONG WITH (E) AN ANNUAL REVIEW OF EACH AND EVERY PROJECT AT THE STATION LEVEL.

IN THE CASE OF REGIONAL RESEARCH THE PROJECT UNDER DEVELOPMENT IS CRITICALLY REVIEWED BY A RESEARCH COMMITTEE OF THE REGIONAL ASSOCIATION OF EXPERIMENT STATION DIRECTORS. FOLLOWING RECOMMENDATION OF THE REGIONAL RESEARCH COMMITTEE, THE PROJECT IS FORWARDED TO CSRS ONLY IF IT MEETS THE APPROVAL CRITERIA OF THE DIRECTORS ASSOCIATION. UPON RECEIPT OF A REGIONAL RESEARCH PROJECT, CSRS ARRANGES FOR ITS CRITICAL REVIEW BY THE COMMITTEE OF NINE WHICH HAS BEEN ESTABLISHED BY THE SECRETARY OF AGRICULTURE FOR SUCH PURPOSES. THE COMMITTEE OF NINE, IN THE DEVELOPMENT OF THEIR REVIEW PROCESS, HAVE AT THEIR DISPOSAL THE ENTIRE SCIENTIFIC COMMUNITY AS ADVISORS AND CONSULTANTS. THUS, EACH PROJECT IS PROVIDED AMPLE OPPORTUNITY FOR CRITICAL ANALYSIS, AND MODIFICATION FOR POSSIBLE IMPROVEMENT.

57-279 O - 87 - 8

Mr. Chairman, you asked that I speak specifically about the mechanisms used to fund research programs within CSRS and the long-term trends in terms of program and mechanism. We use basically three mechanisms: Competitive Research Grants, Special Research Grants, and Base Program Funding. If I may, I would like to discuss the size and scope, the assurance of quality, the strengths and weaknesses of each of these mechanisms. I hope this discussion will illustrate the distinct strengths of each mechanism and each approach I also hope to show that those mechanisms allows the weaknesses of any other specific funding mechanism to be minimized.

COMPETITIVE GRANTS

In FY 1985, CSRS through its Office of Grants and Program Systems managed $54 million worth of competitive grants. In the following program areas:

o Biotechnology	$20,000,000
o Plant Science	$16,500,000
o Animal Science	$ 4,500,000
o Pest Science	$ 3,000,000
o Human Nutrition	$ 2,000,000
o Forestry	$ 8,000,000

The competitive grants program is organized and managed in a manner analogous to the National Science Foundation. It is based upon panels of peers that meet in Washington, D.C. for the purpose of reviewing all proposals, submitted in response to a published call for proposals, by scientists in universities, Federal laboratories, and in industry. The average panel consists of about 14 scientists and generally reviews 140 proposals, ranking them in order of

PRIORITY. THE STRENGTH OF THIS SYSTEM IS THAT IT OPENS COMPETITION TO THE VERY BEST TALENT REGARDLESS OF WHETHER IT IS PUBLIC OR PRIVATE, FEDERAL OR STATE, INDUSTRY OR ACADEMIC. THIS PROGRAM PROVIDES NATIONAL FOCUS AND EMPHASIZES INNOVATIVE IDEAS IN THE SPECIFIC AREAS OF RESEARCH TO BE ADDRESSED. THE MAJOR WEAKNESSES OF THIS SYSTEM ARE THE LENGTH OF TIME AND COSTS INVOLVED IN PREPARING PROPOSALS WHICH GENERALLY ARE FUNDED FOR SHORT-TERMS (FOR CSRS, GENERALLY TWO YEARS AT A TIME). ALL DECISIONS ARE MADE ON A CENTRALIZED AGENCY BASIS. HOWEVER, THE STRENGTHS OF THE PROGRAM FAR OUTWEIGHS THE WEAKNESSES.

SPECIAL GRANTS

IN FY 1985, CSRS ADMINISTERED $32 MILLION IN SPECIAL RESEARCH GRANTS WHICH ARE TARGETED TO SPECIFIC PROBLEM AREAS AND SOMETIMES TO SPECIFIC LOCATIONS. THERE WERE A TOTAL OF 40 PROGRAMS, EACH PROPOSAL OF WHICH WAS PEER REVIEWED. IF THE PROJECT IS STATE SPECIFIC, IT WAS PEER REVIEWED WITHIN THE APPROVED DECENTRALIZED PEER PANEL SYSTEM OF THE UNIVERSITY INVOLVED. FOR PROGRAMS THAT CROSS STATE BOUNDARIES OR INVOLVE SEVERAL INSTITUTIONS, CSRS ORGANIZED A NATIONAL LEVEL PEER REVIEW SYSTEM, BEING CAREFUL TO SELECT ONLY THE BEST SCIENTISTS IN THE FIELDS TO BE REVIEWED. THE STRENGTHS OF THIS APPROACH ARE THAT IT BRINGS DEFINITE FOCUS TO A PROBLEM AREA AND GIVES IT VISIBILITY, PROVIDES FUNDING FOR PROGRAMS WITH A LIMITED LIFE SPAN (GENERALLY IN THE RANGE OF FIVE YEARS) AND ALLOWS BOTH THE ADMINISTRATION AND THE CONGRESS TO RESPOND IN A RATHER SHORT TIME FRAME TO NEW NEEDS. HOWEVER, BY IDENTIFYING A SPECIFIC SITE TO CONDUCT RESEARCH, THE QUALITY OF SCIENCE MAY NOT BE THE HIGHEST AND THE RESEARCH OBJECTIVE MIGHT BE BETTER SERVED IF A WIDER RANGE OF INSTITUTIONS AND LOCATIONS COULD BE CONSIDERED. ADDITIONALLY, THE SPECIAL RESEARCH GRANTS PROGRAM INVITES A SELECTION OF SPECIFIC PROJECTS BY LEGISLATIVE ACTION, WHICH MIGHT NOT HAVE THE SAME SCIENTIFIC CREDIBILITY OR STANDARDS AS THOSE REQUIRED IN THE COMPETITIVE RESEARCH GRANTS PROGRAM.

BASE FUNDING

THE BASE OR FORMULA FUNDED PROGRAM OF CSRS IN FY 1985 INVOLVED EVERY ASPECT OF AGRICULTURAL RESEARCH, INCLUDING BASIC AND APPLIED RESEARCH; PLANT, ANIMAL AND MICROBIAL ORIENTED RESEARCH; MARKETING AND INTERNATIONAL TRADE; RURAL COMMUNITIES AND THE PEOPLE WHO LIVE THEREIN; AS WELL AS HUMAN NUTRITION AND THE USE OF AGRICULTURAL PRODUCTS. THE THREE MAJOR PROGRAMS UNDER THIS HEADING ARE: •HATCH - STATE AGRICULTURAL EXPERIMENT STATIONS, COLLEGES OF HOME ECONOMICS, COLLEGES OF VETERINARY MEDICINE, SCHOOLS OF FORESTRY IN LAND-GRANT UNIVERSITIES ($162.2M); •EVANS-ALLEN - COLLEGES ELIGIBLE UNDER THE SECOND MORRILL ACT AND TUSKEGEE UNIVERSITY ($23.5M); •MCINTIRE-STENNIS - 62 SCHOOLS AND DEPARTMENTS OF FORESTRY, BOTH IN LAND-GRANT UNIVERSITIES AND NON-LAND-GRANT UNIVERSITIES ($13.1M). ON AVERAGE, A DOLLAR IN THIS SHARED FUNDED PROGRAM LEVERAGES IN MORE THAN $4 OF FUNDING FROM OTHER SOURCES.

A STRONG POINT IN FAVOR OF THIS PROGRAM IS THAT IT IS CONDUCTED AT THE STATE LEVEL WITH STATE INPUT AND IS OVERSEEN BY THE STATE LEGISLATURE. MANAGEMENT IS PROVIDED THROUGH THE STATE LAND-GRANT UNIVERSITY OR OTHER ELIGIBLE INSTITUTION. IT INEVITABLY INVOLVES AND HOLDS ACCOUNTABLE THE UNIVERSITY PRESIDENT, THE EXPERIMENT STATION DIRECTOR, THE DEAN AND DEPARTMENT HEADS, AS WELL AS THE INDIVIDUAL SCIENTISTS FUNDED THROUGH THIS MECHANISM. IT ALLOWS RESPONSE TO THE HIGHEST PRIORITY NEEDS IN EACH STATE AND TERRITORY. ITS MAJOR WEAKNESS MAY BE THE QUESTION OF WHETHER THE BEST TALENT TO ADDRESS A PARTICULAR QUESTION IS PRESENT IN A GIVEN INSTITUTION.

THE BASIC MECHANISM FOR ASSURING THE QUALITY OF RESEARCH IS A STATION LEVEL PEER REVIEW SYSTEM THAT HAS BEEN APPROVED BY THE ADMINISTRATOR OF CSRS AND IS ON FILE IN CSRS. ONLY THREE OF THE PARTNER INSTITUTIONS HAVE FAILED TO PROVIDE AN APPROVED STATION LEVEL PEER REVIEW SYSTEM, AND OF THOSE, ONE HAS SUBMITTED A PLAN, ONE IS DEVELOPING A PLAN, AND THE THIRD HAS THE ISSUE UNDER RECONSIDERATION. IN THE CASE OF THOSE THREE UNIVERSITIES, THE SCIENTIST OF CSRS ASSURE THAT A PEER REVIEW IS CONDUCTED ON EACH PROJECT. OTHERWISE, THE PEER REVIEW PROCESS IS CONDUCTED AT THE LOCAL LEVEL. CSRS IS CURRENTLY EXAMINING THE IMPACT AND QUALITY OF THE REVIEW PROCESS ITSELF, AND THIS IS BEING DONE IN COOPERATION WITH THE LAND-GRANT UNIVERSITY SYSTEM.

IN ADDITION, CSRS, IN COOPERATION WITH THE STATE AGRICULTURAL EXPERIMENT STATION SYSTEM SPONSORS 240 REGIONAL RESEARCH PROJECTS, EACH OF WHICH GENERALLY INVOLVES A HALF-DOZEN OR SO STATES AND APPROPRIATE FEDERAL LABORATORIES TO ADDRESS SPECIFIC PROBLEMS OF RESEARCH COMMON TO MORE THAN ONE STATE. THESE PROJECTS ARE THE RESULT OF REGIONAL LEVEL PLANNING, CARRIED OUT IN CONCEPT WITH APPROPRIATE FEDERAL LABORATORIES AND CSRS BY THE FOUR STATE AGRICULTURAL EXPERIMENT STATION REGIONAL RESEARCH ORGANIZATIONS.

SCIENTIFIC EXPERTISE

LET ME TURN MY ATTENTION TO THE ISSUE OF SCIENTIFIC EXPERTISE. CSRS, THROUGH THE OFFICE OF GRANTS AND PROGRAM SYSTEMS, HOUSES THE HIGHER EDUCATION PROGRAM FOR THE DEPARTMENT OF AGRICULTURE. THIS INVOLVES STRENGTHENING GRANTS TO THE COLLEGES OF 1890 AND TUSKEGEE UNIVERSITY AND THE MORRILL-NELSON ACT, WHICH IS

ALSO TARGETED TO THE LAND-GRANT INSTITUTIONS. IN ADDITION, THERE IS A TRAINING GRANT PROGRAM SUPPORTING 300 PRE-DOCTORAL STUDENTS. THESE AWARDS ARE MADE ON THE BASIS OF NATIONAL COMPETITION FROM PROPOSALS SUBMITTED BY PARTICIPATING INSTITUTIONS. A PANEL OF PEERS IS USED TO SELECT THE WINNING INSTITUTIONS AND PROPOSALS. THIS PROGRAM, COMBINED WITH THE OTHER SOURCES OF FUNDING SUPPORTING MASTERS LEVEL, THE PH.D. LEVEL AND THE POST-DOCTORAL LEVEL STUDENTS, PROVIDES THE MAJOR MECHANISM THROUGH WHICH SCIENTIFIC TALENT TO MEET AMERICA'S FUTURE NEEDS IN AGRICULTURE RESEARCH, EXTENSION AND TEACHING ARE TO BE MET. IT ALSO PROVIDES FUNDING FOR STUDENTS WHO ARE IN PROGRAM AREAS NOT SUPPPORTED BY PROJECT FUNDING YET WHO ARE IN DISCIPLINES NEEDED BY AGRICULTURE. INCLUDED IN THIS PROGRAM IS AN EXTENSIVE ANALYSIS PROJECT, DOCUMENTING THE NEED FOR HIGHLY TRAINED AGRICULTURAL SCIENTISTS. THE RESULTS OF THE PROJECT WERE FIRST PUBLISHED IN 1980 AND A REVISION OF THIS STUDY WILL BE AVAILABLE BY THE END OF 1985. LET US REMEMBER THAT ESSENTIALLY ALL OF THE AGRICULTURAL SCIENTISTS OF THE UNITED STATES, INCLUDING VIRTUALLY ALL OF THOSE IN FEDERAL RESEARCH LABORATORIES, ARE PRODUCTS OF THIS EDUCATIONAL SYSTEM.

THE MAJOR MECHANISMS OF INTERFACING WILL BE DISCUSSED AT LENGTH TOMORROW WHEN ASSISTANT SECRETARY ORVILLE G. BENTLEY COMES BEFORE THIS BODY. LET ME SHARE WITH YOU THE FLAVOR OF WHAT HE WILL SAY BY INDICATING THAT THE JOINT COUNCIL ON FOOD AND AGRICULTURAL SCIENCES, A CONGRESSIONALLY MANDATED ORGANIZATION, IS THE ORGANIZATION IN WHICH ALL FEDERAL AGENCIES INVOLVED IN AGRICULTURAL RESEARCH, EXTENSION AND TEACHING MEET THEIR COUNTERPARTS FROM THE STATES, AND FROM INDUSTRY TO INSURE THAT THIS NATION HAS A COORDINATED OVERALL PLAN AND RESEARCH THRUST IN THESE IMPORTANT AREAS. IT IS THE MECHANISM THROUGH WHICH THE

EXPERIMENT STATION SYSTEM PLANS ARE FITTED TOGETHER WITH PLANS FOR RESEARCH TO BE ACCOMPLISHED BY ARS, ERS AND USFS AS WELL AS OUTREACH PROGRAMS OF THE EXTENSION SERVICE. COORDINATION WITH ACADEMIC PROGRAMS IS ALSO EFFECTED THROUGH THE JOINT COUNCIL. THUS, JOINT COUNCIL PRIORITIES FOR ANY GIVEN YEAR ARE INDEED NATIONAL PRIORITIES WITH SPECIFIC EXPRESSION IN THE STATE AGRICULTURAL EXPERIMENT STATION SYSTEM PLANS AS WELL AS THOSE OF ALL THE ORGANIZATION ALREADY IDENTIFIED.

PAYOFF

THE PAYOFF FOR THE UNITED STATES IS SUBSTANTIAL. WITH LESS THAN 20% FUNDING FROM THE FEDERAL GOVERNMENT, THE NATION SHARES THE BENEFITS FROM THE OVERALL AGRICULTURAL RESEARCH SYSTEM, INVOLVING ALL OF THE STATE AGRICULTURAL EXPERIMENT STATIONS [AND OTHER RELATED, RESEARCH-PERFORMING INSTITUTIONS.] THE SYSTEM IS WELL COORDINATED WITH THE AGRICULTURAL RESEARCH SERVICE, THE ECONOMIC RESEARCH SERVICE, THE U. S. FOREST SERVICE AND OTHER RELEVANT FEDERAL RESEARCH AGENCIES. SECONDLY, THERE ARE SIGNIFICANT TRADE-OFFS AS PREVIOUSLY INDICATED, WHERE ONE AGENCY OR EXPERIMENT STATION MAY TAKE AN INDEPTH APPROACH ON A PARTICULAR RESEARCH QUESTION, SHARING THE RESULTS WITH OTHER STATIONS AND THE FEDERAL GOVERNMENT. THE FARMER AND RANCHER BENEFITS FROM THIS IN TERMS OF CUTTING INPUT COST AND THE CITIZEN BENEFITS THROUGH THE AVAILABILITY OF HIGH QUALITY FOOD, FIBER, FUEL AND FOREST PRODUCTS. THE MAJOR FOCUS OF RESEARCH IS IN CUTTING THE INPUT COST, SO THAT AMERICAN AGRICULTURE CAN BE COMPETITIVE WORLD-WIDE.

SUMMARY

LET ME SUMMARIZE BY SAYING THAT CSRS USES THREE MAIN FORMS OF FUNDING, ALL OF WHICH ARE BUILT ON THE BASIS OF REVIEW OF THE QUALITY OF SCIENCE, AND THUS, THE ASSURANCE OF THE QUALITY OF SCIENCE BY MEANS OF PANELS OF PEERS. EACH FUNDING MECHANISM HAS A DIFFERENT FUNCTION. THE BASE FUNDING PROGRAM PROVIDES THE FOUNDATION UPON WHICH THE SPECIAL AND COMPETITIVE GRANTS PROGRAMS OF THE USDA, AS WELL AS THOSE OF OTHER FEDERAL AGENCIES, STATE AGENCIES, AND THE STATE LEGISLATURES, AS WELL AS INDUSTRY CAN BE BUILT. IT'S PRIORITIES ARE SET BY THE SCIENTIFIC COMMUNITY AND ARE CAREFULLY SYNCHRONIZED WITH THOSE OF THE JOINT COUNCIL ON FOOD AND AGRICULTURAL SCIENCES. THE SYSTEM FITS NEATLY TOGETHER, WITH COMPLEMENTARITY IN PROGRAMS AND IN OUTPUT TO FEDERAL LABORATORIES. IT IS AN IDEAL EXAMPLE OF THE NEW FEDERALISM WHERE DECENTRALIZED MANAGEMENT AND ASSURANCE OF QUALITY OF SCIENCE ARE AT THE HEART OF THE SYSTEM. NO NATION HAS EVER BUILT SUCH A KNOWLEDGE-BASED SYSTEM WITH SUCH HIGH QUALITY SCIENCE, AT SUCH LOW RELATIVE FEDERAL COST. THE CONGRESS AND THE PEOPLE OF THE UNITED STATES ARE TO BE CONGRATULATED.

MR. CHAIRMAN, I WOULD BE PLEASED TO ANSWER ANY QUESTIONS.

Mr. FUQUA. Thank you very much, Dr. Jordan.
Dr. Huston.
[A biographical sketch of Dr. Huston follows:]

DR. KEITH HUSTON

Keith Huston serves as Director-at-Large for the North Central Regional Association of State Agricultural Experiment Station Directors. Educated at Wisconsin, Dr. Huston was later employed as a professor of dairy science, specializing in dairy cattle genetics, at Virginia Polytechnic Institute and State University, Kansas State University, and the University of Minnesota. Commencing his administrative career in 1969, Dr. Huston has served as assistant and associate director of the Kansas Agricultural Experiment Station and as director of the Minnesota Agricultural Experiment Station.

Dr. Huston currently is Co-Chairman of the National Agricultural Research Committee (NARC) of the Joint Council on Food and Agricultural Sciences (JCFAS). He has served as Chairman of the Experiment Station Committee on Organization and Policy (ESCOP); Chairman of the Committee of Nine; Co-Chairman of the International Science and Education Council (ISEC) Research Committee, and President of the Agriculture Research Institute, Washington, D.C. His service on national committees and task forces includes: World Food and Nutrition Study, National Academy of Sciences-National Research Council; Panel on Agricultural Research, Office of Technology Assessment (OTA); Ad Hoc Joint Committee on Country Programs, Title XII Legislation, Agency for International Development; Commission on Undergraduate Education in Agriculture and Natural Resources, National Academy of Sciences-National Research Council.

STATEMENT OF DR. KEITH HUSTON, COCHAIRMAN, NATIONAL AGRICULTURAL RESEARCH COMMITTEE, AND DIRECTOR-AT-LARGE, NORTH CENTRAL STATE AGRICULTURAL EXPERIMENT STATION DIRECTORS, WOOSTER, OH

Dr. HUSTON. Mr. Chairman and members of the committee, what I should like to do this morning is to focus principally on the differences in research as it is conducted in agriculture and the Agricultural Experiment Stations, so that you can see the contrast between it and other types of research organizations that you are examining.

I suspect you may have some curiosity as to what a director-at-large is. I am employed by 12 State Experiment Stations, the universities, land-grant universities from Ohio west to Kansas and everything north of there, and there are three others like me in the country. We are part of the glue that holds the State system and makes it a regional and national system, so that's about what I do. I float around the countryside.

The Experiment Stations are a unique organization and have unique funding mechanisms. They differ from the Federal agencies and they differ also from the university groups that you know in typical form. We are proud of the fact that we are a time-tested system. We have been in existence 100 years. We have been to the Hill 100 years and we have been to the State legislatures for as long as there has been a State legislature and a State Experiment Station, and we continue to survive in a relatively competitive, complex world.

Our system has been examined in great detail by countless numbers of scientists and studies, and we keep coming out with a very high return on costs, a high return on investments, and a suggestion that there is sizeable underinvestment. If I may suggest, I

would like to see some of the other sciences subjected to similar examination to see where they come out.

We are a part of the university community. We meet all of the standards of the university community and, despite the fact that Federal grants are extremely important to university professors in terms of their careers, the ultimate decision about whether a man holds a job in a university or not is made by university standards, and those are the standards to which we must submit.

The State Agricultural Experiment Station system is a part of a Federal-State partnership. That was identified by the Congress, just very recently reaffirmed, and in that partnership the State Experiment Stations receive about two-thirds of their funds from the State and about one-third to a quarter from the Federal Government. Now that contrasts with other sciences in the university because other sciences receive about a third to a quarter from the State and two-thirds to three-quarters from the Federal Government, so it's an exact switch between the two. In fact, if you want to do some counting in terms of resources, you find that the agricultural sciences receive more non-Federal support for research than any other group of sciences, including the medical sciences, which is hard to believe, but that gives you some notion of the concern that is spread across the country in our sciences.

Dr. Jordan has talked about our relations in terms of our size. We are the biggest research system in the country and we do a large share of the research, a broad-based research that covers everything from agriculture to forestry to home economics to veterinary medicine to rural development, rural and home community affairs, environmental affairs, and the gamut.

Now what I would like to do very quickly here is to give you a quick feel for the Experiment Stations. I know you have all been there but you may not have recognized it when you got there. The problem is that most of the Experiment Stations are on a land-grant university campus, and most of those campuses are huge places. Aside from the football stadium and sometimes the basketball stadium, it is kind of difficult to remember which building is which.

It turns out that in the State were I live, Ohio, the Station was separated from Ohio State University many, many years ago, and it's off in a little rural city called Wooster. In that same city there is a little land-grant college called the College of Wooster, an excellent, very excellent liberal arts college, has about 1,500 to 1,800 students. It turns out that if you compare the buildings on the College of Wooster with the buildings on the Ohio Experiment Station, it's about the same size, so you get a feel for how big it is in terms of physical plant.

Now the system that is there is characteristically organized like this: There is usually a headquarters unit. It is usually on the land-grant university campus. Now it turns out in California that they've got three places where they put these major centers, because the State is a very large and complex one, but in most States there is a headquarters unit and then there are branch locations strategically scattered across the State. They range all the way from as few as three or four in some of our Northeastern States to as many as 30 or 40 or 50 locations in other States.

The Experiment Stations characteristically are large farms. In my own region—and I know the land holdings better in my own region than in others—in one of my States the station handles something over 30,000 acres. It may have the largest beef herd, the largest dairy herd, the largest swine herd, the largest poultry flock. It may have the largest acreage of corn in the State, so they are heavily involved in production agriculture.

Now among the stations, the California Station is the largest. It is larger than the next two, which are Florida and Texas. It has one of the most diverse agricultures of any of the Stations and in many ways some of the most interesting challenges in the system.

The Stations are part of a land-grant university. The Stations are a part of this university research community, these research universities that people keep talking about. In fact, something like 30 to 35 of our States are part of that research system. Some of them are in smaller institutions but, by and large, they are part of that research community and they meet those same standards.

The partnership, as Dr. Jordan explained, came out of the Congress in the Hatch Act of 1887. We get Federal funds that come to us on a formula basis, about 15 percent of our dollars. Now in California and Florida the dollars are like 3 and 4 percent of the total resources that go into those stations there. In this formula funding, every State participates. You have low administrative costs and the decisionmaking with regard to research is made on the scene, where the action is.

Now the Hatch Act required matching. In other words, the States have to match what the Federal Government puts in and, as Dr. Jordan indicated, you get an awful lot of leverage for that 12 or 13 percent that you put into the States. The attachment to the land-grant university means that there is efficiency of resource utilization because we're tied into the colleges and we're tied into the Cooperative Extension Service.

Now it's significant to recognize that in terms of training the next generation of scientists, that the Experiment Stations are the primary contributor. We kick in 75 percent of all of the graduate assistantships that enable young men and women to pursue graduate work in agriculture. We are the "biggies" in terms of supporting that. We share our facilities, we share our equipment, and we share faculty with the collegiate and sometimes the Extension people.

We have, in terms of an organizational structure, a kind of a hybrid between a Federal line agency in which there is a strong hierarchy, and the university system in which we have a collegial system, in which we get together as a group and try to reach some sort of a decision as a group of equals, so we do have centralized authority. We have a centralized budget. We have a centralized direction to planning, and we have dual responsibility to both Federal and State Government. In fact, I suspect that if you were to look at the Experiment Station in terms of complex political arrangements, it probably is one of the most complex beasts that you could study because it must report both to State and Federal and then, in addition, has grant sources from a whole variety of groups, commodity groups, trade associations, and so on.

Now in that Hatch mechanism, in the Federal mechanism that gave birth to the stations and has helped sustain the Stations, there is a fraction of those resources, about a quarter, called a regional research fund. That regional research fund makes it possible for our States to work together, among themselves and with the Federal agencies—ARS, Forest Service, ERS, and any other agency that wants to participate—in such a way that we can address problems of any magnitude. They can be so little as a county area in a State or so big as national, and we can address them and we can address them in a voluntary way, as we see it appropriate.

Our support, if you look at it in the university community, is direct. We have a mission, and the people who fund us know what we are about. The rest of the university science community by and large receives most of their non-Federal funding as indirect support associated with the graduate programs, associated with research, faculty development activities.

I have been asked to mention briefly some of the trends and policy needs. One that we have lived with ever since I have been in the business is that the user needs seem almost inexhaustible. You keep working away, and they keep coming back, and you get one answer, and they want another answer. So in this perspective our resources have always been limited and we could always use more money. There are some changes, though, in these user needs, in that the problems that they throw at us are more complex than they have been, and you would expect this because you get the simple ones solved and you've got the complex ones left.

The other thing that is interesting is that the solutions as they emerge are adopted much more quickly than they used to be. We used to have a kind of a spare shelf back here where you could put the discoveries, and maybe 5 or 8 years down the road that thing would get used. Those things are picked up immediately. In fact, we have a situation in which many of our best farmers call the Experiment Station scientist—they know him by name—in their particular area and say, "What should I do? What is this situation?"

Now the sad part of all of this is that the scientists are still human beings. They can only do so much, and their minds will only comprehend so much and as the knowledge, the information sources, increase, then we have a tendency on the part of the scientist to specialize and specialize, which means then if you have a problem of a given size that it is going to take more and more scientists to work on that specific problem, so we have a concern now about expanding the number of individuals, the teams, to solve those problems. Now what it really means is that if your resources are stable, level, as ours have been, that you have to pick and choose—despite the pressures—you have to pick and choose more carefully with regard to those problems that you tackle and attempt to solve.

We have considerable flexibility in the Experiment Stations because of the fact that our Federal funds and our State funds come as a lump to the Station—not to an individual scientist, not to a department, not to a college, not to a university, but to a single Station—that those come in lump sum and the allocations then can be made as seems appropriate at the director's level, at the next level of allocation to the science level.

The second feature of these appropriations is that, after 100 years of permanence, they begin to seem permanent and you think you can count on them, and that is very important in developing science programs because you must have some source of sustained funding in order to have the scientists, in order to attack long-term problems, and in order to solve them. We believe that these appropriations, the Federal and State, are very, very significant in this thing.

Now one of the things that is worrying us in terms of the future is, there are new opportunities that keep emerging—biotechnology, genetic engineering, DNA manipulation, computer technology, sensors, and automated research systems. Automated research systems—it is almost unbelievable because you can go in to the lab people, where you used to have to buy them a little bit of glassware and little thing to hang the glassware on and lots of people to do these complex analyses, now you put it in a gadget and it runs out the answer almost as fast as you can feed the stuff in.

On the plant side, in our plant breeding work, we used to hire a bunch of high school and college kids to come in and take each wheat head at harvest time and put them in an envelope, and harvest it that way in order to have the experimental seed. Now we've got machines that are going to do this thing, and we can do three and four and five times as much as we used to do. These new opportunities are extremely important. We don't know how rapidly we can move resources in to take advantage of them.

I would like to finish up by speaking briefly about the roles of public and private. We have always, on the State side, we have always been closely tied to our producers, to our processors, to our marketers, to our distributors, and we work back and forth, trying to respond to the issues as they see them. The separation that seems to be so characteristic on the Washington scene, if I may say so, the separation between Government and industry seems to us at the State level to be a forced relationship—that there may be some real, distinct advantages from a closer relationship and a closer understanding of the two.

Thank you.

[The prepared statement of Dr. Huston follows:]

Statement of

Dr. Keith Huston

Director-at-Large

North Central Regional Association of State Agricultural Experiment Station Directors

Before the

Committee on Science and Technology

U. S. House of Representatives

October 3, 1985

I am Keith Huston, Director-at-Large for the North Central Regional Association of State Agricultural Experiment Station Directors. I report today on behalf of the Experiment Station Committee on Organization and Policy (ESCOP), the national executive committee for all State Experiment Stations.

RESEARCH AT THE STATE AGRICULTURAL EXPERIMENT STATIONS

INTRODUCTION: THE SAES, AN UNIQUE ORGANIZATIONAL MODEL

The State Agricultural Experiment Stations (SAES), individually and collectively, are organized, managed, and funded in a distinctively different fashion than other scientific research organizations funded by the federal government. Similarly, fields of science in agriculture are organized, funded, and sustained in a manner different from most other science fields. Despite these differences, the SAES, with one exception, are all parts of state land-grant university systems and thus a part of the larger university science community. Most land-grant universities are major research universities and thus a part of the research university community so dependent on the federal funds for continued existence and well-being of their research programs. Examination of some distinctive features of the SAES and the fields of science in agriculture may provide insights into options for funding and managing science different from those now common in most federal agencies.

Although the organization of agricultural research and sciences seems perfectly natural to agricultural scientists and users of agricultural science, it often has worried other scientists. Indeed, some have, on occasion, been critical. In that connection, it is important to remember that the organization, costs and benefits of agricultural research and thus of its sciences, have been studied exhaustively. The evidence indicates that the agricultural research model is and has been an highly effective one, so effective indeed that other fields of science, should they ever subject themselves to such study, might be hard pressed to match that record.

NATIONAL ORGANIZATION OF AGRICULTURAL RESEARCH: A FEDERAL-STATE PARTNERSHIP

Public agricultural research long has enjoyed high interest and dedicated support from the House and Senate Agriculture and Appropriations Committees. Those Committees have sought to insure that agricultural research and sciences have met the needs of both users in the food and agricultural system and consumers as well. Because of the major role in agricultural research played by state resources of the SAES, the Congress has viewed the nation's research as a federal-state partnership rather than a predominantly federal activity as is true in other areas. Support for SAES agricultural sciences is about 2/3 to 3/4 non-federal and 1/3 to 1/4 federal. The reverse is true for other university-based sciences.

At this time, public agricultural research is performed principally by 3 USDA agencies, (ARS, ERS, FS-R) each with a restricted mission, and by the State Agricultural Experiment Station System, quasi state agencies with broad missions, each operating under the charter of a land-grant state university. Of the nation's public agricultural research, the SAES perform about 60%; the USDA agencies, about 34%. The remaining 6% is performed by 100 or so other university-based research units.

THE MAJOR FEATURES OF THE SAES: A STATEWIDE SYSTEM IN EVERY STATE AND REGIONAL AND NATIONAL SYSTEMS TOO.

The Congress chartered the SAES in 1887 through the Hatch Act, a remarkable piece of legislation and one for which a centennial will be celebrated in Washington in less than 18 months. In that act and subsequent acts, the Congress set down 7 major provisions which now guide and give form to the SAES.

First, the Agricultural Experiment Station is a State Agricultural Experiment Station. That means it serves the State, not just the SAES nor its parent university. Second, Hatch Act federal appropriations are allocated to the SAES on a formula basis. That means every state participates. It also means lower administration costs, and decision-making at the state level. Third, States must match federal Hatch Act appropriations with state funds. That means that the federal government leverages

state funds and thus multiplies the influence of federal funds. Fourth, the Station is attached to the State's land-grant (A and M) university so that it can relate effectively to undergraduate and graduate instructional programs and extension programs in agriculture chartered there also by federal legislation. That means complementarities in programs can be exploited to increase resource efficiency. Fifth, the Station's chief administrative officer is a Director. That means accountability is centralized in one person who directs activities of the SAES. Sixth, federally appropriated resources are managed by the Station, not the USDA, but with appropriate accountability and responsiveness to national needs as identified by the Secretary of Agriculture and the Congress. That means that decisions are made on the scene by local residents but national interests are protected. Seventh, interstate, interregional, and national coordination and collaboration in research is fostered and conducted among the Stations and with USDA agencies, through a special Regional Research Fund, amounting to one quarter or more of the Hatch appropriations. That means that complementarities in programs among states and among states and USDA agencies at all levels can be exploited to increase resource efficiency.

To my knowledge, such regionally and nationally shared management of research programs exists only in agriculture and only through the SAES. Through long and often controversial, separate evolutionary processes of 100 years or more within each State, the SAES of each state has emerged with many distinctive features, but also with many features common to SAES of other states.

Differences between agriculture and other sciences in research organization and management exist at university, state, regional, and national levels. Each level provides interesting contrasts.

THE SAES IN THE UNIVERSITY SETTING

Within virtually every land grant university system, the SAES and the state's cooperative Extension Service were units legally chartered by the state legislature and located at the land grant university. Each has organized into a statewide system with headquarters units on the university campus and branch units scattered across the state. Those headquarters units

usually are organized into departments corresponding to the instructional departments of the university to which station, or extension faculty belong. Hence, station research scientists are fully integrated into university faculties. Thus, they are subject to the same performance standards as faculty elsewhere in the university. Some university scientists receive or are denied research grants from federal granting agencies according to criteria of the agency. Some judge their success on such events. But faculty always must continuously meet the performance standards of the university community to remain in good standing. Because university standards have precedence, they have higher rank to most faculty.

In many land-grant universities, the SAES and the Cooperative Extension Service are the only administrative units not organized at the discretion of the university and often the only ones budgeted separately from the general university budget. These distinctions are important.

The university, subject to approval by at least its Board of Regents, and sometimes by the state legislature organizes and reorganizes itself into administrative units and subunits as it wishes. Similarly it allocates and reallocates resources from the general university budget to administrative units and subunits at its discretion. The general university budget usually is a complex amalgam of student tuition and fees, state appropriations for higher education, income, research overhead, and gifts and grants from a variety of sources. Bureaucratic allocation of resources according to instructional work loads of colleges and departments is a common feature. However, discretionary allocations also are made.

Historical Perspectives. Prior to World War II, agricultural research in the SAES was the only university-based research to receive substantial direct support from both state and federal governments. Elsewhere in the university, major support for research came indirectly from state governments (or other university resources) by way of instructional programs. That support was to encourage graduate education and faculty development, important research-based elements of instructional programs in the sciences. Though that indirect support cannot be measured in the aggregate accurately, it is large enough to allow professors to spend on the average from 10% to as much as 30% of their work day in research and other scholarly activities. Also it is large

enough to permit such highly labor intensive faculty instructional activities as graduate classes, seminars, and research and thesis direction. That indirect support now has become extremely important to the nation's science programs and to the research programs of the federal government. It creates a permanent national flexible pool of diverse human talents and resources maintained from university resources and yet available on call to the federal government and the private sector to perform research or to train research scientists.

I call this research resource pool the "University Science Indirect Pool," or "USIP." I call the other pool containing the SAES and other directly supported research resources, the "University Science Direct Pool," or "USDP." USIP is determined largely by student demand for curricula created by the faculty. It is student driven. For example, the pool is relatively rich in scientists from the general science fields--chemistry, physics, mathematics, biology and economics--because most university curricula require students to take courses in those fields even though the number of majors in those fields may be relatively small. The pool is relatively lean in scientists from such science fields as forestry, agronomy, entomology, or electrical engineering, because only a few science curricula contain them.

USDP, on the other hand, is determined almost completely by willingness and interest of state and federal governments and private sector organizations to fund research programs. It expands or contracts in size and changes composition in direct response to resources made available for its research. It is "research market" driven.

Scientists in both pools could accomplish more with additional resources. Their needs have been and are brought regularly to the attention of the Congress.

After World War II, university enrollments exploded, thus enlarging the "indirect science pool." Four and two-year colleges acquired more Ph.D faculty, generating indirect science pools there. State governments, however, slowly but steadily fell behind in the proportion of student support they provided.

The Congress authorized sizable expansion in the research activities of many federal agencies. It created the National Science

Foundation largely to capitalize on the university indirect science pool. These research resources ended up being heavily concentrated in high overhead cost private universities and in public universities along the coasts. Universities in southern, plains, and mountain states fared least well.

The SAES expanded, too, but in different patterns. Up to 1960, federal and state resources increased, permitting most SAES to take on a broader range of problems. Since 1960, federal resources have not kept pace with inflation though they have remained relatively stable. SAES in selected states, particularly in the South have received sizable increases in state support while other SAES have expanded only modestly. A few states have reduced support.

As a consequence of the recent recession, most SAES stopped growing and many had to reduce their size as a consequence of reduced state appropriations. That trend is now reversed indicating that agricultural research is still a high priority issue.

Current Perspective and Policy Needs. Current perspectives relative to SAES operations and opportunities are captured in the following points. They also highlight policy issues.

1. Identifying Needs and Opportunities of User Groups: Inexhaustible Needs Force Rigorous Setting of Priorities.

Organized into departments largely along commodity, natural resource, human and community resource, and industrial group lines, the SAES have depended on those departments to maintain close liaison with user groups to identify needs and opportunities. Regular meetings and departmental advisory councils, annual field and research days, and other activities involving users insure that communications flow freely. More general input often is provided by the state legislature, USDA and other federal agencies, and the Congress through the Director's Office. User needs continue to far outstrip resources and force rigorous setting of priorities.

2. Responding to User Needs; Ever More Complex Problems and Faster Adoption of Discoveries.

Most states have from 15 to 40 major commodities and related industries. Most states have from 5 to 10 special topographic, soil, and climatic subregions. Simple problems are readily solved, most many years ago. With each passing year, the complexity of problems increases. That often means larger, longer, and more expensive experiments. New discoveries are adopted much more rapidly. The technology pool has little, unutilized reserve technology.

3. A Scientist as a Lone Problem Solver: Intellectual and Physical Limits of Humans

Scientists design and execute experiments that answer user needs. To solve increasingly complex problems, scientists now specialize ever more narrowly on a single aspect. To solve all aspects requires larger and larger teams. Resource limitations force reduction in the number of problems approached or in the scope of solutions.

4. Resource Availability: Always Inadequate for the Needs

Investments in public agricultural research in a state usually range from 3/4% or lower on gross sales of commodities from that state. Current investments in a scientist average about $150,000 per year. If resources were allocated to a commodity's problems on the basis of the economic importance of that commodity, only commodities producing $20 million or more sales could expect the efforts of one full-time scientist.

5. Resource Flexibility: Constraints of Long-Term Commitments and a One-Time Opportunity

Tenure commitments to specialized faculty and civil service employment standards lock in resources for many years. Thus, employment decisions serve to constrain response of SAES to changing user needs. Retirements of scientists hired as part of the post World War II expansion will provide unusual opportunity for program redirection during the next 5 years.

6. New Opportunities: New Technologies Can Increase Efficiency and Success of Research Systems

Biotechnology, genetic engineering and DNA manipulation, computer technology, sensors, automated research processes and expert systems offer new avenues to increase efficiency and success of the SAES research system.

They will be important influences in resource allocations of the next 5 years. Some have a high price tag. Others offer cost reductions.

7. Changing Roles of Public and Private Sectors in Research: New Opportunities Suggest Redefinition of Roles

Some see research as a sequential trichotomy of basic, applied and developmental activities: basic, primarily in the public sector; applied, in both sectors, and developmental, largely in the private sector. Most now see research as a complex interplay of activities drawn from a continuum of basic to developmental research. Increasing world competition in high technology fields suggest that arbitrary divisions of responsibility among sectors or limiting federal roles to support of basic research now may not be in the nation's best interests.

THE SAES SYSTEM AS A MODEL SYSTEM--A SPECIAL EXAMINATION

Because the SAES system of funding, priority setting and research management is unique, a brief examination of these activities may prove useful.

Funding The old adage "he who pays the piper calls the tune" is true in the SAES. Long-term, stable direct funding of the SAES is a most significant determinant of success. State and federal legislation establish the mission of the SAES; state and federal appropriations support that mission. Dual funding sources enable constraints on one source of funds to be addressed with the other. Because funds are "institutional", i.e., they go to the Station and not to a department or to an individual scientist in the stations, and because the Station Director is held accountable for expenditure of the funds, the Director can exercise considerable influence in allocating resources, and setting

priorities. Similarly, once allocations are made to a department, the department head also can exercise influence. Purchase of expensive equipment and sharing of it and other resources is made possible because the Director has access to a much greater pool of resources than department heads or individual Scientists

Indirect funding through instructional resources of the university can provide only a tiny base, one inappropriately constructed for needs of agriculture. Long-term cooperative agreements with USDA agencies have brought federal scientists to many states. They broaden and strengthen human resources in the state. Grants and contracts from federal agencies offer opportunities for individual SAES scientists in certain fields to expand their operating funds with complementary research investigations. Grants from industry and producers provide added resources in solving problems of concern to those groups (tables 1 & 2 provide details of SAES funding).

Appropriations are made to support the broad mission of the SAES and only occasionally are constrained. They seem to have no major weaknesses. Contracts and grants to individual SAES scientists support the mission of the granting agency and are sharply constrained. The missions of the granting agencies may not complement the SAES mission. When federal grants or contracts become a major resource in a department or to an investigator, they may cause them to lose sight of their SAES mission; and SAES resources drift off target. When industrial or producer grants become a major source, they may cause departments and scientists to focus too strongly on short term problems to the detriment of long term needs. Complete reliance on appropriations may deprive the SAES, its departments, and its scientists of the benefits of competitive entrepreneurship.

Priority Setting Priority setting is an ongoing continuous process involving SAES scientists and administrators and users of their discoveries. In only a few departments, scientists and administrators have little or no contact with users. There, the priority tides generated by the professional societies help establish priorities.

The distinction between basic and applied has little meaning to most SAES scientists. They solve problems by whatever approach is appropriate. The SAES are the nation's largest performers of basic agricultural research. About 40% of the SAES research is classified as basic.

Management When appropriately funded, SAES management draws on the best features of hierarchical management characteristic of federal agencies and the collegial management characteristic of the university. Management decisions in isolation from users are never possible.

Biographical Sketch
Keith Huston

Keith Huston serves as Director-at-Large for the North Central Regional Association of State Agricultural Experiment Station Directors. Educated at Wisconsin, Dr. Huston was later employed as a professor of dairy science, specializing in dairy cattle genetics, at Virginia Polytechnic Institute and State University, Kansas State University, and the University of Minnesota. Commencing his administrative career in 1969, Dr.Huston has served as assistant and associate director of the Kansas Agricultural Experiment Station and as director of the Minnesota Agricultural Experiment Station.

Dr. Huston currently is Co-Chairman of the National Agricultural Research Committee (NARC) of the Joint Council on Food and Agricultural Sciences (JCFAS). He has served as Chairman of the Experiment Station Committee on Organization and Policy (ESCOP); Chairman of the Committee of Nine; Co-Chairman of the International Science and Education Council (ISEC) Research Committee, and President of the Agriculture Research Institute, Washington, D. C. His service on national committees and task forces includes: World Food and Nutrition Study, National Academy of Sciences-National Research Council; Panel on Agricultural Research, Office of Technology Assessment (OTA); Ad Hoc Joint Committee on Country Programs, Title XII Legislation, Agency for International Development; Commission on Undergraduate Education in Agriculture and Natural Resources, National Academy of Sciences-National Research Council.

Behavior and Productivity Implications of Institutional and Project Funding of Research

Maury E. Bredahl, W. Keith Bryant, and Vernon W. Ruttan

A behavioral model of a research scientist is utilized to develop the characteristics of the demand for institutional (IR) and project research (PR) funds. The demand analysis implies a trade-off between the allocative and productive efficiency of IR funding and the research output mix of PR funding. The model is used to evaluate the formula and competitive grant funding of U.S. agricultural research. We conclude that national research policy should be cast in terms of the relative mix of the two systems of support, not in the absolute merits of either system.

Key words: agricultural research, allocative efficiency, demand for research funds, research-funding policy.

In this paper, we analyze the implications of two alternative research-funding schemes. The first, institutional research (IR) support systems, provides funds to support the research program of a particular research institution. Typically, the funds are not targeted to research areas. Rather, the selection of research areas is made by the administrators of the research institution or individual researchers. The second, project research (PR) grant system, provides support through project grants to individual scientists or research teams. The allocation of research effort typically is determined by the granting agency.

Examples of institutional support for research are numerous. IR was the traditional instrument employed to support federal and state mission-oriented research in the fields of defense, agriculture, natural resource exploration, industrial standards, and related areas prior to World War II (Dupree, Stein). The program of federal support for agricultural experiment stations on a formula basis is a prototype of the institutional research system.[1]

In the private sector, the Ford Foundation has provided institutional support for the research program of Resources for the Future since the early 1950s. Institutional grants were also made to Social Science Research Council to enable the Council to operate the Foreign Area Fellowship Program—a program of project grants. The U.S. Agency for International Development (USAID) provides institutional grants in support of the research programs of the international agricultural research centers which are part of the Consultative Group on International Agricultural Research.

The competitive grant program of the National Science Foundation, in which grant requests are received from individual scientists or research teams and evaluated by peer panels, is a prototype of the project research system. Most of the major foundations and a number of federal agencies operate project research grant programs in addition to IR programs. The project research grant mechanism emerged as a major instrument for linking academic research with mission-oriented federal agencies in the late 1940s and early 1950s (Stein).

The authors are, respectively, assistant professor, Department of Agricultural Economics, University of Missouri; professor, Department of Consumer Economics and Housing, Cornell University; and professor, Department of Agricultural and Applied Economics and Department of Economics, University of Minnesota.

The authors have benefited from comments on an earlier draft of this paper by Emerson Babb, Robert Evenson, Walter Fishel, Edward Foster, Don Hadwiger, R. J. Hildreth, Keith Huston, Yoav Kislev, Michael Lea, Willis Peterson, Jean Robinson, Roland Robinson, Theodore W. Schultz, and Burt Sundquist.

[1] Funds allocated to the states under the Hatch Act, except for funds reserved for cooperative regional research efforts, are allocated to the state agricultural experiment stations by a formula based on the number of farms and the size of the rural population in each state. The several sources of federal funds for state agricultural research are identified in the latest annual report of the USDA Cooperative State Research Service. Factors affecting the support for state agricultural experiment stations have been analyzed by Huffman and Miranowski, Peterson (1969), Heady (1961, 1962), and Dalrymple (1962).

Each of the two research management schemes has strengths and weaknesses. The system constraints and the reward systems are very different under IR and PR research management. The next section of this paper presents an analysis of the behavior of individual scientists in an environment characterized by the availability of centralized project grant systems and decentralized institutional grant systems. We then examine the behavior of research administrators under the two research support systems. Finally, we attempt to draw some inferences from the behavior of research scientists and administrators under the two systems for research system efficiency. The analysis presented here provides a theoretical framework for the empirical evaluation of the gains and losses from the two systems of research management.

The Research Scientist

What objectives does the individual research scientist attempt to maximize? And how does the project (PR) and institutional (IR) research grant systems impinge on the behavior of the individual scientist?

The research scientist has been depicted as both hero (Stakman, Bradfield, Mangelsdorf) and villain (Berry). Our perspective is more modest. The typical research scientist is, as a result of inclination and conditioning, prepared to accept a rather high degree of deferred gratification within the professional reward system. In the immediate postdoctoral years, the scientist is usually willing to defer immediate financial reward for an appointment which assures continued professional development—preferably documented by the accumulation of evidence of research productivity in the form of published papers. If professional productivity is accompanied by reasonable advancement in rank and earnings, the initial research orientation is reinforced. If productivity lags or is not accompanied by advancement in salary or rank, there often is a shift in emphasis toward research that is valued by clienteles other than professional colleagues. This shift toward more applied research also may be associated with a transfer to another institution whose program is oriented more toward applied research. During this process the mid-career scientist may also develop certain entrepreneurial skills. These skills may run in the direction of capacity to generate research support from funding agencies and/or to mobilize the interest and the energies of colleagues to focus their efforts around problems of scientific or technical diversification which require a team effort. Development of entrepreneurial skills often comes at the expense of disciplinary capacity and direct involvement in research.

This description is, of course, highly simplified. And our ability to model is inadequate to deal with even this simplified view. However, we are able to identify several key elements of the individual scientist's objective function that appear directly relevant to the scientist's behavior under the institutional and project grant systems. (Since developing the model, our attention has been drawn to a similar model developed by Becker. His models are, however, designed to address different questions.)

The simplified behavior model that we have developed has the following characteristics:

(*a*) Each researcher maximizes some utility function by simultaneously allocating time between teaching, entrepreneurial activities such as seeking research support, actively working on research, and leisure. The use of leisure to represent nonwork related activities is a common methodological device.

(*b*) Research output is determined by the level of research support available to the researcher and the time spent actively working on research. The researcher faces diminishing returns both in the production of research funds and in the production of research.

(*c*) The transaction costs incurred by the individual researcher in obtaining project research support are greater than those incurred in obtaining institutional research support. However, the level of available IR support may be a binding constraint. That is, IR funds may be rationed and become unavailable before the researcher achieves the equilibrium allocation of time which maximizes utility.

(*d*) Income is a positive function of research output and some measure of teaching and/or extension (or public service) output depending on the way in which a particular scientist's appointment is defined.

Our goal is to determine the characteristics of the demand for research funds. Although several factors influence the individual scientist's demand for research funds, only the cost of obtaining grant and formula funds is considered. Factors held constant include the maximum amount of institutional funds available,

the preferences (utility function) of the researcher, the production function of research output, and the rewards from research output (the income production function). Varying the cost of obtaining research funds allows examination of the impact of alternative research management schemes. Only highlights of the model are presented but a detailed description and mathematical exposition is found in Bryant (available from the author upon request).

The results of the model depend critically on the hypothesis that the transactions cost of the PR system is significantly higher than those of the IR system. In other words the marginal productivity of time spent seeking institutional research funds is significantly higher than that seeking project research funds. Most university scientists can quote examples of the colleague who has spent much more time preparing grant requests for the support of summer research than was spent actually carrying out the grant-supported research. It also seems consistent with experience that the greater the degree of centralization of research management, the greater the costs of grant seeking and the costs of the review and allocation process.

The research scientist maximizes utility by allocating his time among active research, grantsmanship, and leisure (all other activities). Thus, the derivation of the demand for research funds (which reflects the allocation of time to grantsmanship) is similar to the derivation of the demand for a consumption good by the utility-maximizing consumer. However, research funds are an input in the production of research output. The derivation of the derived demand for research funds has certain similarities with the derivation of the derived demand for an input by a profit-maximizing firm.

Before deriving the implications of alternative research management programs, the implication of limited IR funds and different production functions for PR and IR funds are developed. The marginal product of time allocated to production of IR funds exceeds that of time allocated to production of PR funds. Logically, any time allocated to producing research funds will be allocated first to IR fund production. Time will be allocated to producing PR funds only upon exhausting available IR funds.

The assumption of greater cost to obtain PR funds coupled with the limitation on IR funds implies the marginal product of time allocated to production of research funds is a step function. The marginal product is illustrated in figure 1. The marginal product curve is derived simply by increasing the amount of time allocated to producing research funds. The conditions for utility maximization are not required to illustrate the characteristics of the marginal product curve.

Initially, any time allocated to producing research funds (T_k) will be used to produce IR funds (T_h). This maps the *ab* portion of the marginal product curve. At *b*, the amount of IR funds available (requiring a time allocation of T_h^{max}) is exhausted. Hence, additional allocations of time can produce only PR funds (T_g). But the marginal product of the first unit of time producing PR funds is less than the last unit producing IR funds. The differential costs result in the discontinuous portion of the curve, labeled *bc*. Allocation of time to producing research funds beyond T_h^{max} produces only PR funds mapping the *cd* portion of the marginal product curve.

To this point, the optimum allocation of time has not been considered. The desired statement of the demand for research funds reflects alternative research management schemes. The cost of obtaining research funds is varied by shifting the marginal product curve illustrated in figure 1. A reduction (increase) in the cost (marginal product) of obtaining research funds shifts the curve upward. To determine the characteristics of the demand for research funds, the marginal products of time producing formula and grant funds are exogenously and proportionately varied.

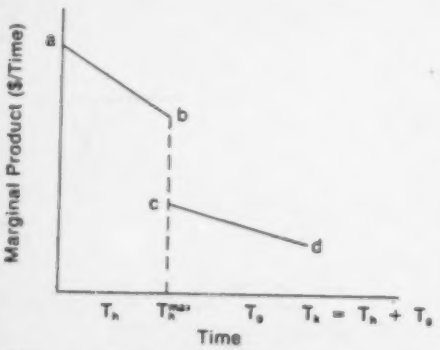

Figure 1. The marginal product of time allocated to obtaining research funds

In the analysis, increases in the marginal productivity of time allocated to producing research funds is synonymous with a reduction in the cost of obtaining research funds. Cost in this context may be thought of as the amount of time in other activities (and the associated income and utility) that must be foregone in order to obtain research funds. That cost reflects the research management system.

Initially, assume the cost (marginal product of time) of research funds is relatively high (low). At equilibrium, relatively little time is allocated to producing research funds (K). Hence, a relatively small amount of research funds will be demanded. Further decreases (increases) in the cost (marginal product) will increase the demand for IR funds until all available IR funds are exhausted (K_h^{max}). This maps the *ab* portion of the demand for research funds illustrated in figure 2.

Further decreases in the cost of research funds will not increase the quantity of research funds demanded. The optimum allocation of time to producing research funds occurs along the discontinuous part of the marginal productivity curve (*bc* in figure 1). Hence, the discontinuous characteristic of the marginal product curve maps the *bc* portion of the demand curve for research funds.

Still further decreases in the cost of research funds induce the allocation of time to producing PR funds (K_g). This maps the *cd* portion of the demand curve for research funds. The effective demand for research funds is *abcd* as illustrated in figure 2. The implications of the step function characteristic of the demand for research funds are now developed.

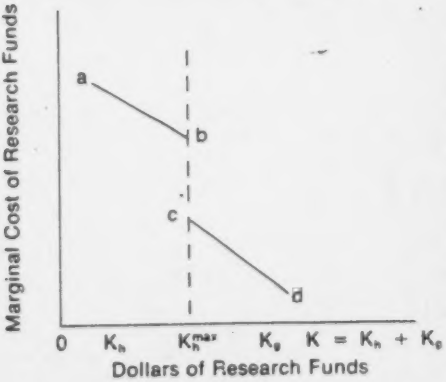

Figure 2. The individual's demand for research funds

First, at any institution there will be those scientists with so low a demand for research funds that they are not constrained by the limit on IR funds. These will be individuals who are very productive in nonresearch activities relative to research and those with high marginal products of labor in research relative to the marginal product of research funds. The former will specialize in teaching, extension, and administrative activities, while the latter will be the "pencil and paper" theorists. Both will operate within the *ab* portion of the demand for research funds and will not be affected by K_h^{max}. Of course, the more affluent the institution, the larger K_h^{max} likely will be for any individual. We would expect, therefore, interinstitutional differences in the proportion of faculty operating in the unconstrained *ab* portion of the curve. Depending on the allocating conventions of experiment stations, some fields may be allocated relatively more than others and so the scientists within these fields likewise will be less constrained.

Second, there likely will be a number of individuals at any institution who operate in the *bc* portion of the demand for research funds curve. Such individuals would demand more IR funds were such funds not rationed. But, they demand no competitive funds (K_g) because the marginal cost of K_g (the marginal value of the foregone leisure) is greater than the increment to income the added funds would bring. The number of such researchers who are thus "immobilized" depends, of course, on the length of the discontinuity, *bc*. It will be longer (and thence the frequency of immobilized researchers greater), (*a*) the greater the difference in the marginal costs of IR and PR funds, (*b*) the better substitutes research funds and researcher labor are in research, and (*c*) the better substitutes teaching, extension, administration, and research activities are in yielding income to the individual.

Third, within the range of the discontinuity, *bc*, while the demand for research funds is invariant, the amount of research done is not. Because he is barred from PR funds by their high marginal cost, the researcher may substitute his own labor for research funds and continue to increase research output, subject, of course, to greater diminishing returns than otherwise would exist. The labor intensity of the research, then, will increase as a result of

the limitation on IR funds and the high cost of competitive funds.[2] This labor intensity with respect to the primary researcher's labor also may involve changes in the research output mix: more theoretical work, more use of secondary data, smaller and fewer experiments, smaller and fewer instances of primary data generation as the research becomes more labor-intensive.

Fourth, another impact of the discontinuous demand for research funds is to increase the labor devoted by the scientist to other aspects of his (her) appointment: teaching, extension, administration. Consulting activities also can be expected to increase. Again, this bias toward nonresearch activities will occur to the extent that the individual has a positive demand for income (is not in the backward-bending part of his supply curve of labor), and the marginal wage rates for the nonresearch aspects of his (her) appointment are positive. Therefore, not only does the limit on IR funds and the high cost of competitive funds increase the labor intensity of the research enterprise of those caught in the discontinuity, it also has the effect of increasing the labor intensity of all other aspects of the individual's job.

Fifth, those not caught on the discontinuity and who have high enough demand for income (consumption) compete for PR funds and operate on the *cd* portion of the demand for research funds curve. The research outputs and incomes of such individuals are higher than those who operate on the *ab* and *bc* portions of the demand curve for the research funds. Because the marginal cost of PR funds is much higher than the cost of IR funds, the research funded with IR and PR funds will be more labor-intensive than the research of those operating on the unconstrained, *ab* portion of the curve. Whether the research done on the *cd* portion of the curve is more or less labor-intensive than those caught in the discontinuity depends on the difference in the marginal costs of PR and IR funds: the greater the difference, the more likely the research of those caught in the discontinuity will be more labor-intensive than those demanding PR funds. One way of looking at this is that as the difference between the costs of the two types of funds increases, more of the scientist's time must be devoted to grantsmanship and less to direct research activities if he (she) is to compete for PR funds.

Sixth, it is likely that a reduction in IR funds with the consequent increased stringency with which remaining IR funds would be rationed among researchers (a shift to the left of K_A^{max} in fig. 1) will increase the difference between the marginal costs of IR and PR funds. As IR funds are increasingly rationed, more individuals will be pushed from the *bc* to the *cd* portion of the demand for funds curve and will compete for PR funds. The increased number of competitors for PR funds will drive down the probability of acceptance of any given proposal and so raise the marginal cost of grantsmanship. A transfer of the reduced IR funds to PR purposes (as the USDA proposed in 1978) will increase either the number of PR projects funded or the level of funding per project and so increase the expected yield per proposal. The net effect of these two changes is unclear. If academics are as risk-averse as recent writings on the economics of academic tenure and retirement suggest, the decline in the probability may well be more important than the increase in PR funds. If so, the marginal cost of PR funds will rise. A possible result of transferring funds from IR to PR purposes, therefore, will be to increase the proportion of researchers immobilized in the *bc* portion of the curve.

Seventh, it is worth noting that given a distribution of grantsmanship skills among scientists, the greater the difference between the marginal costs of IR and PR funds, the greater the likelihood that specialization of function will arise among scientists. The more skilled as grantsmen will specialize in the activity doing little or no actual research.[3] And with the PR funds, they will hire scientists relatively more skilled in research to which they will allocate research funds.

The Research Administrator

An assessment of implications of a project research grant system relative to an institutional research grant system must consider the ef-

[2] In this instance and hereafter when labor intensity is discussed, it is researcher or project director labor that is being referred to. Within the limits of IR and PR funds, other labor (graduate students, postdoctoral fellows, research assistants, secretaries, and the like) may be employed to carry out particular facets of the research.

[3] There is some evidence to the effect that younger scientists are more active in journal publication than older scientists and that the marginal value of a journal article, in terms of income, declines with the scientist's age (Peterson 1973, p. 14).

fects of the two systems on the behavior of the individual scientist. In this section we suggest how the project and institutional research grant systems impinge on the behavior of the research administrators. We shall be particularly concerned with the impact on the behavior of the director of an agricultural experiment station, research center, or laboratory located within a university environment.

Our description of the objective function of the research administrator is largely intuitive. Kaldor (1971, 1978) repeatedly has pointed to the dearth of systematic knowledge about the decision-making processes used by research administrators. Most of the knowledge that we do have is based on casual observation and introspection. Nevertheless it does seem feasible to specify some of the elements that enter into the decisions of research administrators and scientists.

The typical research manager tends to have a view of the world which places a heavy weight on the value of new knowledge and new technology and places a low weight on both the direct and indirect costs of research and of technological change. The administrator visualizes an almost "endless frontier" waiting to be discovered, with limited financial, physical, and professional resources. The administrator's standing, both within his (her) own institution and among outside collegiate and clientele constituencies, is directly related to the ability to assemble or develop a research staff that is recognized for the quality of its work or its value to clientele constituencies. Within public sector institutions, where the salary structure is somewhat bureaucratically determined and has little flexibility at the top, prestige considerations carry greater weight. In the private sector, where the output of the research laboratory is evaluated more directly in terms of the enhancement of the firm's profits, productivity is given more weight.

The net effect of these considerations leads a research director to measure success in terms of the capacity to acquire additional resources and the ability to utilize these resources productively. The measurement of the quality or the value of research output at the individual scientist or research team level is highly subjective, and the management of research enterprises is highly collegial. These factors tend to lead to an emphasis on the quality of the major input, professional personnel, relative to the value of research output. Emphasis on more effective monitoring of research output is greatest in those cases where there is strong clientele pressure. Clientele pressure on research management is reasonably strong in state and federal agricultural research programs because of the close feedback loop between farmers, legislators, and research institutions (Hayami and Ruttan, Guttman).

The above description of the elements that enter into the objective function of the research administrator or manager is not inconsistent with the utility function of the bureau manager that has been suggested in the literature on bureaucratic behavior (Niskanen; Ruttan). In that literature it is assumed that the bureau manager's utility is a function of (*a*) the bureau's output, (*b*) the bureau's discretionary budget. In the case of the agricultural experiment station or the agricultural research institute, we can interpret bureau size in terms of research staff and the output of applied research that is valued by the research institution's clientele. Discretionary budget can be interpreted in terms of funds to support more fundamental (basic or supporting) research and for related professional activities (seminars, symposiums) that serve to enhance the capacity of the research staff or the prestige of the research unit. It represents funds that are not required to meet salaries and other overhead items. This description of the utility function of the research manager involves an even greater simplification of a complex reality than our description of the utility function of the individual research scientist. It does, however, appear to capture important elements of the research manager's motivation.

If incremental growth in research funding is primarily in the form of project rather than institutional research support, as suggested in the introductory section, one effect will be to reduce the discretionary resources available to state experiment station directors. A higher proportion of institutional support funds will have to be devoted to salary and overhead items. Capacity to mobilize resources for problems of significance at the state or regional level will be reduced.

We are now ready to combine our analysis of the effects of the institution research grant (IR) and the project research grant (PR) systems on the behavior of the individual scientist and research administrator, on the efficiency

or the productivity of the research system, and on the strategy alternatives available to research administrators.

Some Research Management and Policy Implications

The goal of a research management system is the production of the socially desired mix of research output at the minimum social cost. Our analysis suggests that the institutional research management system entails lower transactions costs than the project research management system. On the other hand, the project research management system enables the control of the mix of research output at a central (national) level. Advocating one system in preference to the second involves the trade-off between central control and system efficiency.

Research Efficiency

It would be surprising, however, if optimization of the objective functions of research scientists and administrators would lead under most circumstances to system efficiency. System efficiency is a function of the institutional environment, including the structure of incentives and constraints, in which scientists and administrators carry out their professional responsibilities. When we examine the implications for the behavior of scientists and research administrations under the IR and PR systems, some rather clear-cut empirical generalizations concerning system efficiency emerge.

First, the external PR grant system diverts efforts by individual scientists from research to grant seeking and related entrepreneurial activities (Foster 1979a, b). This is why the PR portion (section *cd*) of the individual researcher's demand for funds lies below the IR portion (section *ab*). More directly to the point, in 1978 the U.S. Department of Agriculture (USDA), which administered a competitive grant program of $15 million, received more than 1,100 research proposals involving funding requests for over $200 million (USDA 1978b). Similar ratios have been noted for other grant programs (Leopold). In addition to the time devoted to the preparation of unfunded grant proposals, substantial time also is devoted to peer review and administration.

A major structural feature of the competitive grant system clearly induces excessive allocation of scientific effort to grant-seeking activity. To the individual researcher, the supply of PR funds appears relatively elastic (with respect to effort devoted to grant seeking). Each individual project is small relative to the resources available to the granting agency. In the aggregate, however, the supply of research funds is relatively inelastic in the short run. An increase in the number of projects submissions results in an increase in the share of research resources devoted to grant seeking relative to research and an increase in the bureaucratic resources devoted to grant management. It also may result in smaller average size of individual grants and fragmentation of research effort.

Second, in a system which limits institutional support primarily to personnel support for core scientific staff (such as tenured professors) and capital equipment (such as laboratory space and computing equipment), incremental research costs must be covered by project grants. Over time, a research institute committed to solving a particular scientific and technological problem, adapting soybeans to shorter growing season environments for example, may find its staff responding more to priorities of external funding institutions rather than concentrating its effort on the crop improvement mission. It is not difficult to imagine a situation where a university administration begins to value its agricultural (or space science) research capacity less for the significance of the scientific and technological knowledge it produces than for the overhead generated by research grants or contracts.

This problem appears to be most acute in situations in which institutional research support has been closely linked to, or hidden by, reduced teaching loads. In the 1950s and 1960s many universities used expansion of undergraduate education to support the expansion, almost surreptitiously, of their institutional research support (Keyfitz). This has created two important problems in a period of declining or shifting undergraduate enrollment. Institutional research support by discipline or problem area expanded in response to differential rates of growth in undergraduate enrollment. Likewise during a period of declining or shifting enrollment, institutional support is eroded

57-279 O - 87 - 9

for considerations unrelated to scientific opportunity or technological priority. As noted earlier, institutional support for agricultural research has not been as closely coupled to undergraduate enrollment as in many other areas. There are, however, substantial pressures in some states from university administrators and state legislative committees to conform to university-wide standards with respect to student-teacher ratios. In the future, effective allocation of institutional research resources will require the development of budgeting mechanisms that more effectively uncouple the institutional support for teaching and research activities.

Research Mix

One major advantage that is sometimes claimed for a project grant system is its flexibility in redirecting research effort into areas of new scientific interest or technical concern. Research systems that rely primarily on institutional support have been characterized as limited in their capacity to reallocate scientific and financial resources from traditional areas of concern or staff capacity to new areas. The state agricultural experiment stations in the United States have been criticized for devoting excessive attention to problems of increasing food and fiber production and as unresponsive to environmental and human concerns in a period of changing social values (Paarlberg). In the United Kingdom, the national agricultural research institutes were criticized in the Rothschild report for devoting too much attention to basic research and being unresponsive to the needs of the farmer and the food industry (Ulbricht).

A second argument that is sometimes made for a competitive project grant system is that it creates a marketlike environment for both talent and ideas. This argument frequently is coupled with arguments in favor of a peer review system to assure competent scientific judgment and effective quality control in the allocation of research resources (Cole, Rubin, Cole; Bowers; Gustafson).

Both arguments have a great deal of intuitive appeal when used to support the proposition that a centralized project research grant is itself a powerful force for conformity. We have great difficulty, for example, visualizing how a peer panel might have reacted in 1900 to a proposal from a young physicist named Einstein, who had just published his first professional paper, for support of a project which had as an objective the development of a unified theory embracing mechanics, optics, and electrodynamics—and without resort to conventional laboratory technique.

The Management of Research at SAES

The sources of funds available to U.S. state agricultural experiment stations have consisted primarily of federal funds appropriated to the states on a formula basis and of funds appropriated for agricultural research by state legislative bodies (table 1). Although federal "formula" funds are granted to the state on a matching basis, in recent years most states have supported agricultural research at a level that substantially exceeds the federal matching requirements. In addition to federal and state funds, many state agricultural experiment stations also obtain substantial contract and grant support from private industry, private foundations, the U.S. Department of Agriculture, and from other federal and state sources. The contract and grant support from other federal agencies and other sources has tended to increase slightly more rapidly than the traditional sources of funds.

The last decade has been characterized by a growing lack of confidence in research decision-making processes (Berry; Bonnen; Hadwiger; Mayer and Mayer; Meier; Paarlberg). In the United States the agricultural research establishment has been viewed as unresponsive to environmental, distributional, and humanitarian concerns. New clientele groups have attempted to move concerns such as nutrition, rural development, environmental impact, soil conservation, and the problems of hired workers higher on the research agenda.

Partially in response to this criticism, Congress established a federally funded, competitive, research grant program open to all scientists and administered by the Competitive Research Grants Office of the USDA Science and Education Administration.[4] The FY 1978 appropriation act made a total of $15 million available for competitive research grants. The executive budget for FY 1979 proposed that the competitive grants program be increased by an additional $15 million (table 2). This was

[4] A program of special grants that were competitive among state agricultural experiment stations was initiated in 1970. These funds rose from $2.8 million in 1970 to $16.2 million in 1979 (table 1).

Table 1. Amount and Relative Importance of Federal, State, and Other Funding Sources for State Agricultural Experiment Stations, 1967 and 1977

	1967		1977	
	Amount[a]	Percent	Amount	Percent
Federal sources				
Science and Education Administration (USDA)[b]	53.8	23.1	118.8	19.1

[b] Funds received by states differ from funds appropriated by the amount of direct and indirect federal administrative charges.

offset by a reduction of approximately $11 million in Hatch Act formula funding plus reductions of approximately $1.0 million in McIntire-Stennis Cooperative Forestry Research, $2.0 million in special research grants, and $1.5 million in rural development research (USDA 1978a, c; Strobel). The 1979 appropriations act finally passed by Congress restored the cuts in Hatch Act funds that had been recommended by the administration and continued the competitive research grant program at the $15.0 million level. The executive budget for FY 1980 proposed a continuation of Hatch funding at the FY 1979 level and an increase in the competitive grants program from $15.0 to $30.0 million. The FY 1980 appropriations, however, increased Hatch funding by $9.5 million and the competitive grant program by only $1 million.

Strong support for a program of competitive

project research grants to be administered by the USDA had been made in two reports sponsored by the National Research Council (1973, 1977). The National Research Council recommendations reflected, in part, a judgment that the productivity of agriculture and agriculturally related research could be enhanced by making USDA research support available to scientists in departments and institutions that had not been eligible for support under the formula-funding arrangements.

Administrative officers and scientists at the state agricultural experiment stations also had been generally supportive of the move to expand funds for competitive grants (Babb). Both the National Research Council and the leadership of the state experiment stations, however, had expected that an expansion of funds for competitive research grants would take place in an environment of expanded support for agricultural research. Apparently they did not anticipate the trade-off between the competitive grant and formula funding that emerged in the FY 1978 executive budget proposal.[5]

The argument for expanding support for agricultural research typically has drawn on two sources of support. Agricultural scientists and science administrators have pointed to the technical constraints that must be overcome to meet future food and fiber requirements. They also have argued that technical change leading to lower production costs represents one way of balancing the conflicting claims of farmers for higher incomes and of consumers for restraint in food price increases. Economists have buttressed these arguments with an expanding body of empirical research which has documented the high rates of return to past agricultural research (Boyce and Evenson; Bredahl and Peterson; Arndt and Ruttan). In recent years, they also have worked closely with research administrators to provide *ex ante* rate of return projections.[6] Both the constraint and the rate-of-return approaches suggest substantial underinvestment in agricultural research both in the United States and in most other countries where such studies have been conducted.

Evaluation of Current Research Policy

We have noted that the effect of a system which appears optimal to the individual scientist or to the individual research manager in a world characterized by limited institutional support and substantial project research support alternatives is to (*a*) induce both excessive allocation of professional resources to grant seeking and (*b*) contribute to the disintegration of the capacity to undertake major mission-oriented applied research programs. These two sources of inefficiency can be reduced by utilizing an institutional research strategy as the primary device for the support of mission-oriented applied research and for basic research which directly relates to the needs of an applied research program.

There is substantial evidence to support the claim of efficiency for the institutional support system. High rates of return have been attributed to the state and federal agricultural research systems in the United States, to a number of older research institutions in former colonial countries (such as the Rubber Research Institute of Malaysia), and to the older units of the CGIAR-sponsored international agricultural research system (Evenson; Evenson, Waggoner, Ruttan). It would be extremely difficult to imagine that the long-term research effort required to develop the high-yielding clones which have revolutionized productivity in the Malaysian rubber industry could have been accomplished on the basis of a series of project grants from a colonial research secretariat in London.

The inferences drawn from agricultural research are consistent with the experience of a number of highly productive industrial research programs. Mansfield et al. (p. 157) have documented rates of return to industrial research in the same range as the rates of return to public sector agricultural research. The more productive private research programs typically have been those which have combined long-term sustained support by a firm with a sufficiently broad product line to be

[5] Dr. M. Rupert Cutler, Assistant Secretary for Conservation, Research, and Education, USDA, appeared to be surprised by the results of his own budgeting efforts. In response to committee questioning on this point he responded (p. 91, 92), "That apparent relationship was unintended. By that I mean the relationship between beginning a competitive grant research program open to all agricultural scientists and the level of the Hatch Act budget request." Cutler went on to explain that many of the programs of the USDA (entitlement and regulatory programs) are legislatively determined. Given a budget ceiling, the remaining funds available for agricultural research programs are fixed. Thus the only available method to initiate the competitive grants system was the reduction of other research areas.

[6] For a review of the methodologies for estimating *ex ante* values of return see Fishel, Puterbaugh, and Shumway. For an attempt to develop *ex ante* rate-of-return estimates see Araji, Sim, and Gardner.

able to utilize a substantial share of the product of a major "in-house" research program (Mueller).

Finally, one can point to the productivity of a number of long-term institutional research support activities by the private foundations. The support by the Carnegie Institution for the fundamental studies on inheritance in maize by George H. Schull is a classic example (Sprague). The Rockefeller Foundation support for the research program of the Office of Special Studies in the Mexican Ministry of Agriculture over several decades (from the mid-1940s to the early 1960s) established the basis for the research program of international research centers which are part of the Consultative Group on International Agricultural Research (CGIAR) system. The Ford Foundation institutional support for the research program of Resources for the Future has been a major factor in establishing resource economics as a major field of economic research in the United States.

Qualifications and Conclusions

Long-term institutional research support also can become a source of inefficiency. Institutional research programs are subject to the danger of becoming too conventional or of losing a sense of urgency with respect to their mission. We noted earlier that project grant support has been defended on the basis that it forces a research system to become more responsive. We find no fault with this argument as long as project research support remains relatively small—as long as its impact is to encourage the exploration of new opportunities within the broad research mission of an institution

There are also other devices for offsetting geriatric tendencies in a mature research institute. The development of cost-sharing arrangements between public research institutes and clientele groups, or user representation on boards of directors or advisory committees, and use of periodic peer review panels are among the possibilities. An important factor in the case of the state agricultural experiment stations has been their location within a university environment. The interaction between graduate training and research and the opportunities to draw on professional capacity in related fields have contributed to research productivity.

Another argument which must be dealt with is whether a competitive PR support system is an effective way of taking advantage of the research capacities that exist outside of institutionally funded research programs. A major argument in favor of the new USDA project grant program is that it would be able to draw on professional resources in departments that do not receive experiment station funding and in institutions that were not part of the land grant system. An analogy often is made with the project grant programs of the National Science Foundation, which frequently supports the research of individual scientists in institutions which have very little institutional research capacity.

This argument is only partially compelling. The United States has been reasonably successful in evolving a dual system of colleges and universities in which those institutions that are capable of organizing effective graduate training and research activities are sharply differentiated from those that do not possess such capacity. The major research universities probably have greater capacity to manage efficiently a program of research grants based primarily on the quality of individual projects than a central granting agency such as the USDA or the National Science Foundation.

For the colleges and universities which do not have substantial graduate programs, faculty research must be justified primarily on the basis of contribution to the viability of the teaching programs. A limited commitment of faculty effort to scholarship and research contributes to the vitality of undergraduate teaching programs. Even in institutions that are primarily committed to an undergraduate education mission, our experience on university and agency research review panels leads us to believe that institutional support for a program of small grants would be more efficient than a grant program that is centralized in a Washington agency.

In our view, the current argument about the merits of institutional (IR) and project (PR) research support more appropriately is cast in terms of the relative mix of the two systems of support than in the absolute merits of either system. We do, however, insist that the issue of efficiency in the allocation and use of research resources is important. The productivity of agricultural research judging from historical rates of return has been high. This places a heavy burden on those who would argue for

the shift of resources from institutional to project support to demonstrate that such a shift would either enhance the productivity of the existing level of research support or draw substantial new resources into the agricultural research system.

Mr. FUQUA. Thank you very much, Dr. Huston.

Let me ask all three of you, what type of program do you have in your research that funds the replacement of facilities and instrumentation in these research facilities, or is there a systematic approach? Now I'm really thinking of the laboratories in the universities or Experiment Stations and so forth.

Dr. KINNEY. Mr. Chairman, let me respond first, and I can respond only for the ARS laboratories, but we use a part of our support funds to do that on a continuing basis. We haven't always in the past done as good a job as we should do because we were a dispersed organization, but now that we have a centralized management of ARS facilities, program, and so forth, we have begun a program that is taking inventory of all of our facilities and equipment, and we are giving specific attention to updating all of our equipment.

We are in amazingly good shape, the survey is showing, but we are going to get on a basis where we are going to take a percentage of these support funds each year and look at the needs, not on a local basis but on a national basis, so that we will be replacing things like electron microscopes and so forth.

Mr. FUQUA. How much are you talking about, percentage?

Dr. KINNEY. We're talking about now 3 to 4 percent of our base funds, and that doesn't seem very much but when you're talking about a half a billion dollar budget, it amounts to quite a bit. In addition, we do have $12 to $14 million of repair and maintenance funds each year, the funds that have regularly gone from program into this sort of thing, so we are very much concerned about it but we are going to solve it in-house. We are not looking for any special appropriations.

Mr. FUQUA. Dr. Jordan.

Dr. JORDAN. Mr. Chairman, this is perhaps one of the most important topics for the land-grant and university-based research component for agriculture that we could address, and the philosophy behind the bill that you have authored and that which was submitted by the administration in the farm bill are exactly parallel, and recognize the significance of this. The expectations are that in the university system we are in the process now of trying to ascertain very accurately what it is in agriculture, but it will run somewhere in the vicinity of 15 percent of the total budget from the Federal Government to the States.

What happens is that what we are hunting for firm data on that is to find out from the individual stations the buildings and facilities that they have already approved by the State screening system, so they are not "wish lists," and then if they want to have another category that says, "Well, they have been approved on the campus level but not by the State," that gives us something more to take a look at, but very hard data in that regard, so the principle is very sound.

Mr. FUQUA. Dr. Huston.

Dr. HUSTON. At the State level there is considerable variation but I think I can generalize in this fashion: that buildings and fixed equipment normally are dealt with by the State legislature as

a separate request from the universities. The process within the university with regard—and this is where the Experiment Stations are more tightly tied to the university than they are in many other ways—in a general sort of a way, the priorities with regard to building are established by a campus committee which reports to a vice president or a president or some sort of a group of this sort and, having served on one of those, I can tell you that what happens is, you develop a list. The list is very long. You inch your way up year by year by year, trying to get there, and you may as a part of the committee get to the top of the list, only to find that when the president goes to the legislature, you are back down in third place. There is a little slippage involved in the process, if I may say so. But, nonetheless, we are part of the university community so in that context we operate that way.

Now we have had in many States, when the situation got desperate enough, we have had some of the agricultural people in the State go directly to the legislature and say, "We must have that building," and they have done it that way.

With regard to movable equipment, there are two features of this. We have the capacity as a unit to provide equipment in competition with other resources, and in this we rely on our department heads and scientists and say: "Well, now, you've got the choice. Here are the dollars. You go ahead and tell us what you want most." Up until very recently their choice was heavily on faculty because of the specialization and the need for the faculty, but increasingly now as the opportunity presents itself—many of our scientists are beginning to retire—they are beginning to shift over and invest more heavily in equipment. The start-up costs as you bring these young scientists in are much larger in terms of new kinds of equipment than they were before. In some of our fields—for example, in some of our crop production fields, where tractors and fields and harvesting equipment were normal parts of their experimental stuff—we have that on hand, but it is some of this new computer, biological, biotechnology equipment that is particularly difficult.

Mr. FUQUA. Yes, Dr. Kinney.

Dr. KINNEY. We find that scientists and research leaders very often are not much different than farmers. When times are tough, they mind the farm. They don't paint the building; they don't replace the equipment. So that is one of the reasons that we ofttimes find ourselves in difficult circumstances.

One of the criteria that we have established and we are adhering to in ARS, because we do monitor research programs annually and approve them, one of the criteria for approving a research project is, "Do they have the equipment available to do the research?" If they don't have the equipment, then it reflects bad management on the part of the research manager and the project is not approved, so it's a strong motivating force.

Mr. FUQUA. Dr. Kinney, what percentage of your work is done in-house or at Federal facilities—I'm thinking of something like Beltsville—versus university research?

Dr. KINNEY. About 30 percent of our research projects are conducted at or on land-grant university campuses, cooperative with

them, and the number of scientists ranges all the way from 1 or 2 up to 35 or 40 on a university campus.

Dr. HUSTON. Let me give you an answer from the State side. There are, nearly as we can tell, about 600 scientist-years from the Federal agencies on our State Experiment Station campuses. We don't normally talk about the State resources that go into Federal research but I made an estimate several years ago and came out with somewhere between $30 to $40 million that was easily accounted for without taking into consideration land, farms, buildings, livestock, and things of this sort that it's terribly hard to put a value on.

Mr. FUQUA. Well, what percentage is the difference between the formula grants under the Morrill Act and some of the others that have been enumerated, versus Competitive Grants that were referred to? How does that break down?

Dr. JORDAN. The relative size of projects?

Mr. FUQUA. No, I'm talking about the percentage of your budget that would be——

Dr. JORDAN. Of our budget? $162 million in the last fiscal year on the Hatch Act, $23 million in the Evans-Allen, and $13.1 million in forestry research, so just about $200 million, and the Competitive Grants Program is $54 million. That is a separate category, and then also the special grants is another $34 million.

Mr. FUQUA. Dr. Jordan, you mentioned a relationship that you had with NSF and NIH and so forth. There seems to be a gradual accumulation of joint boards and advisory panels and so forth, more than there are in some of the other Federal agencies that are involved in that type of a program. Is that a healthy thing or has it gone too far toward advisory groups, enough that the structure in the future, would you recommend it be reduced or changed any?

Dr. JORDAN. I think the issue that is legitimate here is that the quality of science has to be measured by peer scientists, and once you have done that, the management effort has to be done separately from that, so in the Experiment Station system that is pretty well separated into two categories. There is an awful lot of advice input and maybe at a given station level, Dr. Huston, there are so many advisors from various commodity groups and what not that it becomes a burden but, in terms of the assurance of quality, we try to constrain that to a reasonable number of scientists reviewing it. The average number of people that go out on a site visit for CSRS—and this will be, now, a review of a program every 4 to 6 years, a thorough review of program at each site—there will be about 4 to 5 people on that review team. It depends on the complexity of the discipline being reviewed, but the minimum number needed to assure quality and yet at the same time not to get out of hand.

Mr. FUQUA. Dr. Kinney, do you wish to comment on that?

Dr. KINNEY. Yes, I do. I guess maybe as times get more and more difficult—and by "times" I mean the budgeting, funding for all of the things that we should do or would like to do—it seems we get more and more advice, because the users of our product become concerned, so we have had a proliferation in my opinion of many, many advisory groups. I attended a Brookings Institution meeting yesterday and listened for most of the day to a lot of consultants

who told us what ought to be done to solve the farm crisis problem, and so forth and so on, said what the Congress should do, what the Department should do, and they didn't tell me anything I didn't know when I walked in there. It seems to me we should spend more time talking about strategy. We know what to do. The thing is, how do we do it? So yes, NSF and NIH, I think their groups are good because generally they are giving scientific advice and not complaining about all the things we're not doing that we should do.

Mr. FUQUA. Well, we have in the Department of Energy, we have the ERAB, the Energy Research Advisory Board made up of private citizens or nonagency people, and NASA has that in their space science area, an outside distinguished panel that says, "These are the categories that we think need high priority." They are not necessarily telling you what to fund or not to fund but these are broad categories, and then you take that advice and try to apply it in your own basic need. I just wonder sometimes if Congress is at fault, too, in mandating some of these, and I was just wondering if the structure was such that it might be an inhibitor in the future.

That was more of a comment, rather than a question, but——

Dr. KINNEY. It takes a lot of time. We take a lot of time, and I have looked at research priorities for many, many different groups, including industry groups and others. The question I always ask is, What have you left out? We get a list of priorities and it includes everything, so I don't know what good the list is. When we set priorities, we talk about what we're going to not do and what we're going to do.

Mr. FUQUA. Yes.

Dr. HUSTON. I would like to put a little different perspective in from the State end. We probably, in comparison with Federal groups, are much more heavily involved in these sort of interrelationships. While they sometimes prove burdensome in terms of time demands, we feel that they keep our scientists and our administrators looking very closely and knowledgeable about the problems as they emerge, and while the seat gets a little hot sometimes, nonetheless you've got your friends there that are interested in what you're doing. They are criticizing you when they think you're wrong, and I think it helps move the system along very effectively.

Mr. FUQUA. All right. Dr. Kinney, I was looking in your statement. I think you said something about that you were developing a long-range plan for agricultural research for 30 or 40 years. In developing that strategy, did you come up with examples of new methods of funding or different management techniques or even other approaches and so forth in that study?

Dr. KINNEY. No, we didn't. This program plan, of which I think a copy has been provided to you, simply outlines what we see as the technologies, the science that is going to be necessary in the next 20 to 50 years, and it outlines the role that we see ARS playing. We are not talking about the total system, only ARS, and a number of groups were very disturbed when we came out with this plan, simply because they didn't see their needs in there. It was simply because we didn't see satisfying their total needs as a mission of ARS, so this is strictly a plan that establishes the science, the approach, and the policies. Perhaps the most important part of

that document is at the end, where we establish six policies for ARS that say, This is how we are going to operate.

Mr. FUQUA. What percentage, or maybe some ballpark figure, in the allocation of funding that goes to individual investigators versus to an institution, is there a breakdown of that?

Dr. HUSTON. Yes.

Mr. FUQUA. Should it be more one way than the other, or——

Dr. JORDAN. In the case of the Department of Agriculture and the Cooperative State Research Service, we have a breakout of about 75 percent that's identified for institutional funding, perhaps a little larger than that, and the remainder of it on an individual basis, which would include the SBIR program.

Mr. FUQUA. Do you think that's an adequate balance?

Dr. JORDAN. We think that the base funding is exceedingly important, because it's on that base that you build the spikes of excellence, if I may indicate that, and use the specific directed funding and individual funded programs to fit into that. What we think is needed is a more—a larger volume of money in the individualized Competitive Grants Program, but not at the expense of the base program. That would be penny-wise and pound-foolish, to erode that foundation.

Mr. FUQUA. Dr. Huston.

Dr. HUSTON. Let me draw a contrast in our Experiment Stations. We have competitive programs in the Department of Agriculture which are agriculturally oriented. There are also similar programs at NIH and NSF—NSF largely oriented toward the particular science, NIH largely toward the medical issues. We draw money in the Experiment Stations from all three sources. As you compare them, the nice thing about the Competitive Grants in agriculture is that they keep your scientists who get the grants working in agricultural problems. When you go to NIH, the flavor is obviously human medicine. Now in our animal work that isn't so bad. When you go to NSF, the flavor is largely science-oriented, and there there can be a drifting away from the specific interest, for example, in wheat or corn or grapefruit or something, onto something more esoteric but scientifically important, and so we think that there is a difference in the kinds of grants and the kinds of agencies that our award grants, in terms of maintaining a stable program.

Mr. FUQUA. Do you think that NIH and NSF ought to use the concept of base funding or formula funding for its universities?

Dr. JORDAN. If you were to talk to them, Mr. Chairman, they view this as one of the weaknesses in their program. that there is an inadequate amount of institutional funding. The National Science Foundation at one time had such a program. It has washed away in the meantime, and the NIH has a very modest one at the moment, the biomedical sciences——

Mr. FUQUA. But it's not a formula, though. It's more of a block grant.

Dr. JORDAN. That's right. It's a biomedical sciences support grant program, and it's driven by how much other biomedical science, NIH-funded biomedical science, is carried out at your institution.

We have some formulas that are somewhat hybrids in that regard. In particular, the program for funding animal health and disease takes into account the size and scope of the animal indus-

try in the State. It takes into account the size and scope of agriculture in that State, and it also takes into account the size and scope of your capacity to perform biomedically-related research, so all of those characteristics are put together and it works fairly well.

Mr. FUQUA. Mr. Brown.

Mr. BROWN. Thank you very much, Mr. Chairman.

I think all of you gentlemen recognize that this task force is looking at the overall position of science, federally-supported science, and we're trying to determine the strengths and the weaknesses of each of the different methods that the Federal Government uses. The chairman's last question is indicative of that search. We find increasing, not complaint exactly, but an awareness of the considerable amount of time spent by scientists in the preparation of grant requests, for example, which is a defect of the Competitive Grant system, and sometimes these scientists look longingly at the formula system as a substitute for that, or longer period grants at least, and we need to balance these factors.

You have all been enthusiastic supporters of the ag research system, and I am also, but in looking at that system we want to also see what its weaknesses might be. You know overall this system, which is the best research system in the world—as you pointed out, Dr. Jordan, and I'm sure you all feel—has produced a very sick agriculture. Now that may not be cause and effect, but we need to find out why we have that situation.

Something similar is true in our biomedical and health research. We have the best system in the world. We have been the leaders in the world, and yet we have the most expensive health care system and one which is not the world leader in terms of infant mortality and longevity and some other factors of that sort. We need, from the standpoint of a committee looking at science policy, to understand why we don't have these corresponding beneficial effects from what we perceive to be excellent systems of science support, and that's a very difficult question.

Dr. Huston, you said one thing that caught my eye or ear, and I'm sure Mr. Fuqua's, that the percentages of Hatch Act funding in California and Florida are amongst the lowest in the Nation. Would you like to explain just why that is the case?

Dr. HUSTON. They are not among the lowest. They are among the least of the share of the budget. For example, in California, as I recall the number, Mr. Brown, around 4 or 5 percent of the total California budget comes from Federal funds, from Hatch funds. The same is true in the Florida station.

Now in States there is a little bit of what you were hitting at, that California and Florida, with as large agriculture as they have, don't get as much of the Federal funds as some of the other States that have less, but the formula is a formula based on farmers and people in agriculture, not on the output. I must admit candidly that those of us in the Midwest wouldn't mind one bit if the formula were shifted over to a sales basis because we, like Florida and California, would gain considerably from it.

On the other hand, as we look at our brethren in the Mountain States, and those up in the Northeast and some of the Southern States, the Hatch funds attract State resources there, and in terms

of the total system the formula that provides some for even the least has some distinct benefits at the system level.

Mr. BROWN. This formula was handed down by Moses, was it? [Laughter.]

Dr. HUSTON. No, or it was almost, yes. May I speak to that? I was on a committee in 1971, as a fresh administrator, asked to examine this formula, and I was imbued with the notion it ought to be related to cash sales in agriculture, and I was trounced within 10 minutes of the discussion. I simply couldn't construct a majority.

Mr. BROWN. Well, I'm sure you gentlemen all know that we tried to alter the formula this year, and we ran into some of those objections from some of the States which benefit from the present formula. As I understand the situation now, Dr. Kinney, you are going to do a 1-year review, or the Department is, of alternative formula systems that we could use. I think that language is in the farm bill, if we ever get it passed.

Well, that was the alternative, a very common alternative that we use: If you can't get something through, study it for a year. I hope, however, that if that language does pass, that the Department of Agriculture will propose some reasonable alternatives that would at least slightly increase the weight of the agricultural sales. Nobody is asking that we drastically alter the formula. It has never been drastically altered. Every change has merely been added on top of the existing formula, so that it produces a very slight modification.

Dr. KINNEY. Congressman Brown, Loretta Owens just informed me that Dr. Greenwood, the Administrator of the Extension Service, will be heading the study of that.

Mr. BROWN. Yes. Well, we'll look forward to seeing some results from that.

We are undoubtedly trying to finish before——

Mr. FUQUA. Right. I apologize for asking so many questions.

Mr. BROWN. Oh, no. Your questions were excellent, Mr. Chairman.

I had a comment. I have a number of questions but won't be able to go into them. I wanted to make a comment. Dr. Jordan, you said something about the fact that no nation has ever built such a knowledge-based system with such high-quality science at such low-level cost, and I concur with that. I think you also pointed out that most of our agricultural scientists come out of that system. I'm sure you are aware that a good share of the agricultural research in the Third World also come out of that same system, and that needs to be added to the values that this system has produced. I think it's a world asset, not just a U.S. asset.

Getting back to the point I originally made—Why do we have a sick agriculture with such a good system?—what has happened to the policy sciences in agriculture over the last 20, 25 years—to agricultural economics, to agricultural sociology, to some of the other sciences which might look at the overall conditions of agriculture, and not just those factors which increase its productivity and happen to decrease its profitability at the same time? What has happened in that area?

Dr. JORDAN. There are—this is probably the number one topic of interest in the agricultural research community of the university

because of what appear to be no answers coming out. Part of that is that the disciplines themselves have found that the complexity of the situation makes it difficult to predict, and they say that's not a good enough answer.

The second one I think is more important and that is, because of the complexity the disciplines have found it very difficult to define and state clearly the researchable question. So as a part of the planning effort in the Experiment Station system, a major effort has been put forth and some planning money provided by CSRS to the Ag Economics Association and the World Sociology Association and so on to do exactly that, with the idea that you have got to have a clear statement of the researchable questions, know what it is you can find the answers to, and relate those to the problem areas, and perhaps that will be helpful.

Mr. BROWN. I suppose part of the problem is also that this is where agricultural problems intersect with the rest of society——

Dr. JORDAN. That's absolutely correct.

Mr. BROWN. Run up against political ideology and other things.

Dr. JORDAN. That's right, and so if the Europeans play on a different policy base than we do, it doesn't make really for an open market, does it?

Dr. HUSTON. Let me comment just quickly from some experience that we had in the Midwest. We had, at one of our institutions, policy people who developed what they perceived as an appropriate approach. When it hit the State in the published form, the political multiplicity of views—if I can say it that way—emerged, and that policy unit was discontinued in the university, so it is a very sensitive issue. We have talked some in the Midwest, where we have traditionally some very keen policy activities, about whether there is a way one might insulate these. You need to have them separate from the Federal Government so they won't take the Federal line, but at the same time you maybe have to have them separate from the State government so they won't get entangled in State affairs.

Mr. BROWN. Gentlemen, I have a lot more questions but we better bring an end to this at this time. I will defer, Mr. Chairman.

Mr. FUQUA. Thank you, Mr. Brown, and I want to thank all of you for joining us this morning. It has been very helpful and, as Mr. Brown pointed out, what has been done in USDA over the years has been certainly an excellent example of what Government can do in trying to fund some of the seed research—not "seed" in the normal context, but much of the very important research—and it has proven that if we hadn't done such a good job, we wouldn't have such a problem over on the floor right now trying to pass a farm bill. [Laughter.]

Thank you very much.

[Whereupon, at 12:10 p.m., the task force recessed, to reconvene on Friday, October 4, at 9:30 a.m.]

[Answers to questions asked of Dr. Kinney, Dr. Jordan, and Dr. Huston follow:]

United States Department of Agriculture
Agricultural Research Service
Office of the Administrator
Washington, D.C. 20250

RECEIVED
NOV [illegible] 1985
COMMITTEE ON SCIENCE AND TECHNOLOGY

October 31, 1985

Honorable Don Fuqua
Chairman, Committee on
Science and Technology
House of Representatives
Washington, D. C. 20515

Dear Mr. Chairman:

Pursuant to your request of October 11, 1985, there is enclosed a packet of information which responds to the written questions submitted to supplement the record of the October 3, 1985, hearing of the Science Policy Task Force.

As always, Mr. Chairman, we appreciate the interest of your Committee in our programs and I appreciated the opportunity to meet with the Task Force.

Sincerely,

T. B. Kinney, Jr.

T. B. KINNEY, JR.
Administrator

Enclosure

1. How do Agricultural Research Service programs compare with the science programs of the science agencies in their effects on science and on the universities?

Dr. Kinney. They are similar in that ARS research programs contribute significantly to the scientific knowledge base of the broad areas of biological and physical science. Most of the approaches to solving problems and finding research solutions in ARS are similar to scientific research conducted by other research agencies in the Federal government. However, research conducted by ARS is mission-oriented and focused on solving specific national problems for agriculture, whereas many of the science projects in universities are focused on answering biological and physical questions rather than development of technology for the solution of a specific problem for a user.

2. Acting on the priorities developed in agricultural research, how do you handle the phasing out of research activities which no longer have any priority attached to them?

Dr. Kinney. Projects in ARS have a 3- to 5-year duration. As these projects are completed, an assessment is made by the scientists and managers in ARS on whether to continue the work in the same problem area. If priorities change, resources are normally redirected at, or near, the end of the project completion date. If a major change is made in the area of work, the user group for that research is contacted prior to the redirection of the work. Although the user group may not concur in the redirection, particularly if the new research is in a different commodity or area of interest to the user group, the reasons for the redirection are explained to the user group. For the most part, industry and user group priorities are the reasons for the redirection of the research. Thus, there is generally concurrence for the redirection of research activities.

3. Agricultural research has always had to focus some fraction on problems arising suddenly in the actual practice of agriculture, or in response to what a recent report called "nature based agricultural emergencies." How large a percentage of all agricultural research falls in this category, and what is the longer term trend in such research?

Dr. Kinney. The percentage of resources in ARS required for solution of emergency problems is relatively small. I would say it accounts for less than 5 percent, within a given fiscal year. Although ARS has given much attention the last few years to focusing research to meet the needs of USDA action agencies and other user groups, the projection of resources required to meet emergency needs does not appear to have changed over the past 10 years.

4. In today's environment, how successful are the several components of the agricultural research system in attracting each year a number of the younger researchers into agricultural research work? In the coming decade, how do you see the prospects for recruiting good researchers into agricultural research?

Dr. Kinney. We think we have been reasonably successful in attracting and retaining top, young scientists to ARS in recent years. ARS has initiated a postdoctoral program which has resulted in hiring young, highly selective investigators to work with our best and leading scientists. Already, some of these young scientists have been hired permanently by ARS and others have returned to the university or entered the private sector to work on agriculturally related problems.

During the past 4 years, there has been a particularly intense recognition of the challenging agricultural problems and a recognition of the needs to train scientists in areas critical to agriculture. University administrators and faculty are responding by encouraging quality graduate students to work on the difficult but exciting biosagricultural problems. One of the motivating factors has been the infusion of dollars through the USDA competitive grants program and another is the concentrated effort of the National Science Foundation to focus on increased funding support for the plant sciences. In the coming decade, additional support will be needed to strengthen graduate student programs in the biosciences, especially the animal area, if a continuous supply of well-trained agricultural researchers is to be assured.

5. You noted that the Agricultural Research Service has recently developed a plan covering the research opportunities for the next 20 to 50 years. We have often heard from other scientific institutions that such long-range planning for science is almost impossible because of the uncertainty about which discoveries will be made in science. How are you able to do long-range planning for agricultural research?

Dr. Kinney. In the ARS Program Plan, we attempted to project the research needs and opportunities for the long-term, 20-plus years. In addition to this Program Plan, however, we developed a six-year Implementation Plan. This six-year plan is used to guide our research and budget process on a year-by-year basis. We agree with the observation of other scientific institutions and agencies that such long-term planning for science is, at best, unsure. However, much of today's technology was developed from scientific research initiated about 20 years ago. Thus, we think it is imperative that we have a long-range plan as well as a six-year plan for operating purposes. We fully recognize that the planning process must be continuous and even a six-year plan must be adjusted annually in light of new research findings in agriculture and other fields of science and to changing needs in agriculture. Most of the national problems in agriculture do not change within a decade, but scientific approaches to solving these problems must be adjusted as new information is available.

6. In other areas where science provides a strong input to technological innovation, it has often been said that the agricultural system, including the close connection between research, extension and education could serve as a model. Yet the repeated attempts, for example, by the Department of Commerce 20 years ago and more recently by some of the States, to apply the agriculture model to other industries have not had much success. Have you any thoughts why that is so?

Dr. Kinney. Most assessments of the effectiveness of the agricultural system are based on the fact that U.S. agriculture has been able to produce an adequate, wholesome, and safe food supply for the American public. Agriculture has essentially had only one goal: the production of an abundant supply of food and fiber. Perhaps the goal of the agricultural system has been more specific than that of the other industries. However, at the present time there is widespread concern that the "agricultural system" may not be adequate to meet the evolving needs of agriculture.

7. Is the present structure for the management of agricultural research going to remain the same 25 years from now? Or, to put it another way, if you could write a new Act to replace the Morrill, Hatch, Evans-Allen, McIntire-Stennis, and other Acts now governing the system to take effect in year 2000, how would you structure the agricultural research system as you think about the long-range future needs and the less useful parts of the present system?

Dr. Kinney. No, I do not think the management of agricultural research is going to remain the same over the next 25 years. In agricultural research, we have seen a substantial change in the past 5 years in the relationships of public and private sector research and development. We have seen a much greater increase by the private sector in projecting the needs to research managers and scientists in the public sector. I think it is imperative that the linkage between public-supported agricultural research and the private sector continues to increase. It is my opinion that the management of agricultural research will continue to change to meet this and other needs over the next two decades. ARS was reorganized two years ago to assure that we would be responsive to those changes that are taking place.

If I could write a new Act to replace those existing for agricultural research, I do not believe I would make substantial changes. The present system, on net, has been highly effective; and I see no reason it should not continue to remain highly effective. There have been instances where parties involved, including managers of agricultural research, have not utilized the flexibilities within the system to adequately meet the needs for agriculture. The problems, in my opinion, have to do more with individuals or groups than they do with constraints of the existing Acts.

8. As you look over the total Federal program of support for scientific research, do you see any aspects of the agricultural research system, whether it is in management, project selection, planning, funding mechanisms, or the dissemination and use of research results, that could be applied to research support in other areas other than USDA's research programs?

Dr. Kinney. Although ARS research is mission-oriented, science for agriculture has a great deal in common so far as management, program selection, planning, funding, and research approaches with other Federal agencies. This is true for several reasons. Scientists in a given disciplinary field use the same techniques, methodology, and scientific approaches to test a hypothesis or focus on a problem regardless of species. Scientists and research managers in most fields of science attend many of the same research meetings and have a relatively high level of interaction with peers without regard to their organization affiliations. A significant percentage of scientists and research managers in ARS have worked previously in other Federal research agencies and State and private universities. There are many scientists and research managers in other Federal research agencies who were formerly in the Agricultural Research Service and/or State Agricultural Experiment Stations.

9. In developing the long-range plan for agricultural research, did you come up with any recommendations apart from the subject matter itself, such as for example, emphases on new methods of funding, different management approaches, and so forth?

Dr. Kinney. In developing our Program Plan and the 6-year Implementation Plan, we first assessed the mission and role of the Agricultural Research Service. We did not come up with new methods of funding, but rather placed emphasis on the need to more clearly define the established national problems that ARS should address. As part of this process, the management was changed to give more focus to national programs and less focus to State and local research needs. A system was also developed to realistically establish research priorities based on user needs.

10. In a recent study by Dr. Lipman-Bluman, it was found that agricultural research, perhaps more than other areas of government-supported research, is subject to political influences. Specifically, such things as priority setting, laboratory closings or staffing are addressed by the Committees of the Congress. Without necessarily getting into specifics, would you comment in more general, philosophical terms on the advantages and disadvantages to a research program of such close interaction with the political system?

Dr. Kinney. The interest of national commodity and other user groups is reflected by actions of Congressional committees on ARS research programs. This interest by Congressional committees, on net, is very positive. The negative impacts on research programs as referred to in your reference to the Lipman-Bluman report are not a problem for ARS. For the most part, this level of interest in use of tax dollars ensures that ARS programs will be focused on relevant needs of the users and that technology transfer will be fast. The only constraints on management of Agricultural Research Service programs by Congress and by user groups relate to location closures and to shifting of funds from one commodity or user group to another. Congress will occasionally object to our attempts to consolidate programs by closing unneeded facilities. Overall, I think that Congressional and user group interest in ARS activities is a plus.

United States Department of Agriculture | Cooperative State Research Service | Office of the Administrator | Washington, D.C. 20250

NOV 0 1 1985

Honorable Don Fuqua
U.S. House of Representatives
Chairman, Committee on Science
and Technology
Washington, DC 20515

Dear Mr. Chairman:

In response to your letter of October 11, 1985, I have prepared the enclosed statements.

I appreciated having the opportunity to appear before the Task Force and look forward to further interactions as you continue your assessments.

Sincerely,

JOHN PATRICK JORDAN
Administrator

Enclosures

1. How do Cooperative State Research programs compare with the science programs of the science agencies in their effects on science and on the universities?

Dr. Jordan. The Cooperative State Research Service is a science agency and its programs, like those of many other science agencies, are carried out primarily through universities. In this regard, CSRS programs have had effects similar to those of other Federal programs that support individual project leaders, but do so in the field of agriculture. They differ in one major respect. Specifically, the 50 State legislatures have at least matched the CSRS funding, and many have matched $3 or more for each CSRS Federal dollar provided.

Many important advances can be attributed to projects supported by CSRS funds. CSRS programs have also brought an additional dimension to research; that of a national, coordinated program to bring together researchers at many institutions to address particular problems. By encouraging this kind of networking, expertise at different institutions has been brought together to address problems in ways that would be impossible for individual institutions. CSRS is currently providing over $35 million in funding to programs where two or more State agricultural universities are working together on common problems.

2. Acting on the priorities developed in agricultural research, how do you handle the phasing out of research activities which no longer have any priority attached to them?

Dr. Jordan. Research projects are approved for no more than five years. Base or formula-funded research projects are reviewed at the end of the period and are either revised or terminated, based on the results of the review. If revised, they are subject to a new peer review and must receive favorable recommendations before they are approved for continuation. Special Grant projects are not continued beyond a maximum of five years.

3. Agricultural research has always had to focus some fraction on problems arising suddenly in the actual practice of agriculture, or in response to what a recent report called "nature based agricultural emergencies". How large a percentage of all agricultural research falls in this category, and what is the longer term trend in such research?

Dr. Jordan. Emergencies arise from time to time in the agriculture sector, and require a short-term shift of emphasis in research effort. However, with the strong base program of research, and with emphasis on fundamental research, the system is capable of responding quickly to such emergencies. It is estimated that only about 5% of the research effort falls in the emergency category and the percentage is not expected to change much in the long-term. As more basic research is done, it is much easier to respond to emergencies.

4. In today's environment, how successful are the several components of the agricultural research system in attracting each year a number of the younger researchers into agricultural research work? In the coming decade, how do you see the prospects for recruiting good researchers into agricultural research?

Dr. Jordan. Currently, there is growing evidence of deficits of college-educated agricultural scientists, educators, and other professionals in both the public and private sectors. In 1980 our data indicated that demand exceeded supply in several fields of study including: Agricultural Engineering, Food Science, Plant and Animal Molecular Biology and several others. We believe that unless these trends can be reversed, they will impede future U. S. agricultural efficiencies. Between 1977 and 1983, baccalaureate enrollments in agriculture at our Land-Grant Universities declined approximately 30 percent. During this same time period, graduate enrollments diminished by a factor of 5 percent. At the doctoral level, over 32,000 degrees are being awarded annually in the U.S. Only about 1,000 of these are in agriculture and natural resources. And, of these 1,000, approximately 32 percent are earned by foreign students who return to their native country subsequent to graduation. The residual domestic supply of Ph.D. graduates amounts to only some 680 annually available to the U.S. labor force--approximately 14 per State. Projections through the mid-1990's suggest a continuation of these trends.

5. In other areas where science provides a strong input to technological innovation, it has often been said that the agricultural system, including the close connection between research, extension and education could serve as a model. Yet the repeated attempts, for example by the Department of Commerce 20 years ago and more recently by some of the States, to apply the agriculture model to other industries have not had much success. Have you any thoughts why that is so?

Dr. Jordan. I expect that some of the answer relates to the timing with which the agricultural programs were initiated. The Land-Grant Universities were established early in the development of scientific agriculture and they served as a logical base from which to build research and extension programs at a later date. With this focal point established early in the country's history, as agriculture and its infrastructure developed it was logical to build around the support systems of the Land-Grant Universities and their programs, in research, extension and education. In the case of other industries the opportunities to establish similar programs in the same time frame are no longer possible. Another factor may be vested interests that do not see that it is to their best advantage to establish such a system for certain industries.

6. Is the present structure for the management of agricultural research going to remain the same 25 years from now? Or, to put it another way, if you could write a new act to replace the Morrill, Hatch, Evans-Allen, McIntire-Stennis, and other Acts now governing the system to take effect in year 2000, how would you structure the agricultural research system as you think about the long-range future needs and the less useful parts of the present system.

Dr. Jordan. This is always an interesting kind of a question to consider. The various legislative authorities and management structures for agricultural research have evolved over a period of many years. Programs and relationships have developed in a stepwise manner into an effective system that is providing high quality information to agriculture. The Hatch, Evans-Allen, and McIntire-Stennis Acts all called on the States to designate universities and name directors to take responsibility for the programs. The States themselves are much more than matching this Federal investment. This management approach has led to the State Agricultural Experiment Station system that is decentralized, but tied together in a network that responds to national needs as well as State and local needs. With these base programs in place, it has been possible to capitalize on their capabilities to address special problems through special grant and competitive grant project funding.

Looking to the future, I see a maturing of the Evans-Allen institutions and their becoming fully integrated into the system. Animal health research will be funded through its own acts as is forestry today. Home economics research will become better defined, as will agricultural economics, with clearer statements of researchable questions and will warrant substantially greater funding. Agricultural research will develop closer relationships with other basic science agencies, especially NSF and NIH.

For the State Agricultural Experiment Station system, I anticipate that in the year 2000 the needs of agriculture will be met through types of funding similar to those currently in use. That is, I would want institutional funding to maintain a decentralized infrastructure and base programs for agricultural research. Building on this base and other research capabilities, there would be programs of project grants to address special problems. There also should be training grants to insure adequate trained personnel. One important change I see is a larger proportion of agricultural research funding in competitive grants than now--maybe as much as 50 percent. The reason for this is to more fully use all kinds of talent in all kinds of institutions to address and resolve agricultural issues. A second important change I see is a more orderly approach to providing replacement of equipment and facilities. This will apply to both worn out and obsolete equipment and facilities.

7. As you look over the total Federal program of support for scientific research, do you see any aspects of the agricultural research system, whether it is in management, project selection, planning, funding mechanisms, or the dissemination and use of research results, that could be applied to research support in other areas other than USDA's research programs?

Dr. Jordan. One question that has been receiving considerable attention in recent years is whether or not the present practice of major funding for science going via project grants is the most efficient and effective way to fund research. The amount of time spent in preparing and reviewing proposals is considerable. There also is the question of how to maintain the base of research from which the individual project grant proposals can be prepared. In agriculture the approach of having a portion of the Federal funding made available on an institutional basis, with management provided at the State or university level, has been seen as a good balance in this regard. An advantage of this decentralized management has been the shared responsibility by the principal investigator, the Department Head, the Dean, and other university officials for successful conclusion of projects. To promote high quality research we have imposed peer review requirements to be managed at the university level but, nevertheless, applied to all projects funded with these institutional grants. Decentralized management has been particularly effective in agricultural research where problems vary from one geographic region to another. It has also ensured a base program from which high quality proposals can be developed in response to needs for increased effort on particular programs, as in our competitive grants program. I believe that further use of institutional funding should be considered. Agriculture's Current Research Information System is developing into an effective, easily accessible science information system that can serve as a model for other areas. Finally, a well organized outreach effort like our Cooperative Extension Service is extremely important in getting research results applied by all users.

8. In developing the long-range plan for agricultural research, did you come up with any recommendations apart from the subject matter itself, such as for example. Emphases on new methods of funding, different management approaches, and so forth?

Dr. Jordan. Funding for the total research effort put forth by the State Agricultural Experiment Station system comes from several sources. Each source of funds fills a specific niche, but the base funds for the entire system come from the combination of State appropriated funds and formula funds from CSRS. Peaks of excellence and focused productivity can be accomplished by using all other sources of funds. We now see value in base or institutional funding, special grants to areas of special need, competitive grants for national focus using talent in all types of institutions, and training grants to ensure a reservoir of trained, talented people. We are also looking at approaches similar to the McKnight Foundation's program projects, or nested projects, as the organizational base.

9. In a recent study by Dr. Lipman-Bluman, it was found that agricultural research, perhaps more than other areas of government-supported research, is subject to political influences. Specifically, such things as priority setting, laboratory closings or staffing are addressed by the Committees of the Congress. Without necessarily getting into specifics, would you comment in more general, philosophical terms on the advantages and disadvantages to a research program of such close interaction with the political system.

Dr. Jordan. An important advantage to close interactions with a political system is that it provides an opportunity to keep the Congress well informed on the programs and results of the agricultural research system. As long as we have effective programs and a good product to sell, we are in an enviable position of having the ear of the body that ultimately determines the funding level for the program. It also provides for early interactions and dialogue on problems that the Congress may see developing. The primary disadvantage of this close interaction arises when individual interests surface in directives that are not in the best interest of the total system.

If Congressional earmarking begins to direct a major portion of the program (more than about 5%) it could threaten the effectiveness of the system-wide program planning which has considerable citizen input.

Washington, D. C. 20515

Dear Mr. Fuqua:

Enclosed are my responses to questions for the record of hearings on "Science in the Mission Agencies and Federal Laboratories". Your questions were reviewed with great interest by administrators of State Agricultural Experiment Stations. I received suggestions from Station Administrators of the States of Connecticut, New York, Michigan, North Dakota, Indiana, Georgia, Wyoming, Colorado, Maryland, Mississippi, Minnesota, and from the Directors-at-Large for the Southern, Northeastern, and Western Regions. They were all much impressed with the perceptiveness about and genuine interest in agricultural research.

Sincerely,

Keith Huston

Response to Questions about the

Statement of

Dr. Keith Huston

Director-at-Large

North Central Regional Association of State Agricultural Experiment Station Directors

Before the

Committee on Science and Technology

U. S. House of Representatives

October 3, 1985

1. Acting on the priorities developed in agricultural research, how do you handle the phasing out of research activities which no longer have any priority attached to them?

In phasing out activities, one rarely finds activities of no priority. Rather the choice is among activities of greater or lesser and often shifting priority as research problems change and the resource base changes.

Research scientists, individually or in groups, are the principal resources and molders of research programs to solve problems. Scientists are specialists; they only can solve certain kinds or parts of problems. Many problems cannot be solved until teams of appropriate specialists are available. Because most research problems are solved only after years of effort, scientists must make relatively long career commitments. These factors cause research programs to be more stable than changeable. But scientists do change and so do programs.

Change occurs in a number of ways. Each scientist routinely uses flexibility within his specialty to accommodate changes in priority. In agriculture, where all research resources, including faculty time, are budgeted through a project system, those changes are readily seen when project accomplishments are reviewed annually and again at the end of the project's 3- or 5-year life. Increasingly stringent project management has become a major force in effecting incremental change.

Program redirection also can be effected easily when new faculty positions or vacancies in old positions are filled. Some Stations have added a few new positions in recent years. Most, however, have had only realignment of vacant positions. Many stations now have an unusual opportunity to effect change because faculty members added during the post World War II expansion are just now retiring. But those opportunities are not without risk. Increasingly rigid tenure standards emphasizing accomplishments of individuals rather than teams and shifts to employ more scientists qualified only as basic scientists cause change but also add inflexibility to programs.

Programs also have been changed by shifting faculty work assignments (e.g., from research to teaching or vice versa), a procedure used commonly elsewhere in the University. In agriculture, where research and teaching are budgeted separately, net gains to each function are relatively modest a determination often not makable elsewhere in the university. In recent years, considerable attention has been given to career redirection as a possible means of change.

Finally, during the 1980's, many Stations retrenched programs opportunistically when recessions forced states to cut budgets. Most stations permanently eliminated low priority projects and programs only gradually as vacant

positions permitted reconfiguration. Those retrenchments also heightened attention to long range planning.

2. Agricultural research has always had to focus some fraction on problems arising suddenly in the actual practice of agriculture, or in response to what a recent report called "nature based agricultural emergencies". How large a percentage of all agricultural research falls in this category, and what is the longer term trend in such research?

Responding to "nature based agricultural emergencies" is a normal activity in agricultural research and extension. Some emergencies require "trouble shooting" or "quick response". Many emergencies are prevented by "maintenance research".

The proportion of research devoted to "trouble shooting" is influenced by (1) the volatility of the state's agriculture and (2) the division of responsibility among research, extension and state diagnostic units and the resources available to each. Many emergencies are of recurrent types; solutions are known or at most require minor alterations through research. The large and permanent concentration of diverse research, extension, and teaching specialists on land-grant university campuses provides an important diagnostic resource that can be enlisted rapidly to safeguard the state's agriculture. Recent "trouble-shooting" research in two states required 15% and 25% of the station's resources. Cash reserves to support such large emergency research measures are difficult to maintain now in times of such tight budgets; scientists supported largely from individual grants are reluctant to respond.

Maintenance research, research to hold gains already made and to prevent emergencies, likely exceeds 50% of all agricultural research. Such research likely will increase in importance as the inherent productivity of our plants and animals moves higher and higher. For producers, when times are hard, emergencies can be the final straw, so prevention through maintenance research is important.

3. In today's environment, how successful are the several components of the agricultural research system in attracting each year a number of the younger researchers into agricultural research work? In the coming decade, how do you see the prospects for recruiting good researchers into agricultural research?

Currently, there are two visible trouble spots in attracting younger researchers into agricultural research. One is in recruiting graduate students who can be both an agricultural science specialist and an agriculturist. The other is in attracting general science Ph.D.s, usually trained outside agricultural colleges, to research agriculturally important species or problems, oftentimes as faculty of agricultural science departments. The latter

will correct itself as general scientists learn more about the agricultural research system. The former, however, is more difficult.

During the last two decades, specialization in science has increased markedly; the number of farm-reared undergraduates has declined. Agricultural researchers now are more stratified with respect to their knowledge of and interest in agriculture. Science specialists who are also agricultural generalists are essential components of the land-grant and experiment station system because they effectively develop readily useful new technology. They, thus, attract support not only for their work but also for that of their more restrictively specialized colleagues.

Unless special inducements are available to undergraduates, graduates and research faculty, the problem will persist. Unlike general and medical sciences, agricultural sciences do not generate pools of post-doctorate researchers from which research faculty can be recruited. Thus, the problems must be approached very early in the career of a prospective research scientist. The problem is exacerbated by the need for careful targeting and scaling of inducements. The number of scientists in some agricultural science specialties is very small and in others, very large. Shortages may be short- or long-lived.

Support for training agricultural scientists is an important by-product of agricultural research programs. The experiment stations are the principal source of resources for graduate education (3/4 of the graduate assistantships and most of the support resources). Shortages of trainees in some specialties indicate that research programs alone cannot be counted on to produce their own replacement scientists automatically.

4. If you were faced with a doubling of the funds available to the USDA of funds for research, how would you divide these new resources among formula funding, block grants, and individual project grants?

Doubling USDA funds in agricultural research would be a welcome and important gain to all states. Choices among funding mechanisms likely would differ among states because institutional needs vary. Doubling USDA funds in states which receive only a modest fraction of their resources from USDA would not have the same institutional impact that it would in states that derive a larger fraction of their funds from USDA.

Ranges suggested in allocations are as follows: Institutional (Formula), 50-60%; Topical or Regional Special Grant (Block Grant), 10-25%; and Topical Competitive Grant (Individual Grant), 20 to 30%.

The expanded institutional base would permit special attention to urgent equipment and instrumentation needs and refurbishing of facilities, postponed

because of recent retrenchments. It also would permit expanded interdisciplinary team building so important in agricultural systems research.

The regional share of the expanded Hatch formula funds combined with a regional block grant would permit states to enlarge their interdisciplinary and interstate cooperative research. That might also contribute to the development of interstate, multistate, and regional pacts relating to cooperative specialization among states on selected research issues.

5. In other areas where science provides a strong input to technological innovation, it has often been said that the agricultural system, including the close connection between research, extension and education could serve as a model. Yet the repeated attempts, for example by the Department of Commerce 20 years ago and more recently by some of the states, to apply the agriculture model to other industries have not had much success. Have you any thoughts why that is so?

Failure of other components of science to duplicate agriculture's success may have occurred because the following conditions did not prevail:

a. One or more clientele groups must have research needs that are economically or socially important to them and which cannot be met easily or effectively elsewhere (e.g., by private consultants, contract research firms, in-house research units)

b. Those research needs must comprise a class of problems, or be subdividable into classes of problems, each class sufficiently homogeneous as to be solvable by a specialist and sufficiently large as to require major commitment of time by a specialist for 4 or 5 years.

c. The aggregate research needs must be sufficiently numerous and diverse as to require the attention of 3 or more specialists who look to the same administrative unit for major support.

d. The needs of the clientele groups must be economically or politically important enough to elicit firm and long term commitment by state government, federal government, or universities.

e. Research scientists must believe that satisfying their clientele groups is their ultimate goal. Too often, some lesser goal may take precedence, such as earning a consulting fee or satisfying only one's self that the research was capably done.

6. Is the present structure for the management of agricultural research going to remain the same 25 years from now? Or, to put it another way, if you could write a new Act to replace the Morrill, Hatch, Evans-Allen, McIntire-Stennis,

and other Acts now governing the system to take effect in year 2000, how would you structure the agricultural research system as you think about the long-range future needs and the less useful parts of the present system?

The dual state-federal agricultural research system has worked well for many decades. Federal legislation affecting agricultural research has been changed periodically over the years in response to need.

In the next 25 years, the pivotal role of the State Agricultural Experiment Stations in federal responses to regional, national, and international issues in agriculture will need legislative attention. Required specifically will be federal legislation providing (a) greater incentives to state governments to support agricultural research, and (b) greater opportunities and incentives for stations to work together and with USDA and other federal agencies on multistate, regional, and national issues.

In the next 25 years, patterns of federal resource allocation among federal intramural programs and federal-state partnership programs likely will receive much greater attention.

Complementarities of the state and federal systems are being altered. Because the SAES of almost every state have had sufficient resources to maintain comprehensive, balanced research programs, they have responded in some measure to most "local" and "state" priorities and to many "regional" and "national" priorities. Thus, the SAES filtered out many high priority needs that otherwise might have competed legitimately for attention from the USDA agencies. The SAES serve as a buffer for the USDA agencies. Similarly, but in a much smaller way, USDA agencies buffer the SAES from federal or national priorities that might have call on federal appropriations to the SAES.

Growing complexity of research problems, increasing relative costs of doing research, greater specialization of scientists, and unusual opportunities to broaden the science dimensions of existing research fields are reducing the comprehensiveness of SAES programs. They also are siphoning off resources once used to attract and train graduate students as replacement scientists. Disquietingly, the current economic crisis in agriculture has heightened the demand for research to provide greater economic efficiencies.

Two obvious responses offer little help. States long ago exploited in fullest measure the opportunities for interstate, regional, and national collaboration provided by federal funds. Federal agencies are reducing what scattered research efforts they had that contributed simultaneously to "state" and "local" needs.

What this all likely means is that new demands for research to solve crucial problems at state and local levels will emerge in the USDA and Congress.

7. As you look over the total federal program of support for scientific research, do you see any aspects of the agricultural research system, whether it is in management, project selection, planning, funding mechanisms, or the dissemination and use of research results, that could be applied to research support in other areas than USDA's research programs?

Several features of the agricultural system might be useful elsewhere: some in university-based research programs, others in federal agencies.

In university-based research programs, the following might be useful:

a) Use of the project system as an informal, internal contract between the research scientist and his institution in accounting for all his research time, salary, and other expendable resources and for his accomplishments. External grant resources would be combined with institutional research resources not now separately budgeted.

b) Greater use of institutional research support mechanisms by federal agencies rather than individual research projects. Included might be greater emphasis on such approaches as matching; interinstitutional cooperation (as with RRF); formula allocations by demographic, geographic, or economic criteria; formula allocations by research capacity (federal or non-federal, or both) These mechanisms would support the mission of the agency and provide simultaneously for a greater diversity of initiatives and approaches in research.

c) Longer project support by awarding grants for longer periods.

In federal agencies, the following might be helpful:

a) Broader and greater interactions with user groups in assessing importance and priority of research.

b) Greater reliance on external review of research accomplishments.

c) A broader perspective of the role of federal agencies in science.

d) Greater and deliberate reliance on competition among state and federal performers and managers (e.g. USDA's intramural and partnership programs).

8. In developing the long-range plan for agricultural research, did you come up with any recommendations apart from the subject matter itself, such as for example, emphases on new methods of funding, different management approaches, and so forth?

Within states, the breadth, diversity and urgency of research needed from the agricultural experiment station always are quite evident. During the last

10 years, resources have been stretched tighter and tighter in efforts to respond to needs. What seems to be emerging from the most recent long-range planning efforts of the SAES is universal recognition of the need to work and plan together more intensely to identify urgent common priorities, expand the resource base, and use current resources more effectively.

With regard to expanding the resource base, approaches center on (a) developing more effective ways of displaying the dynamics and evolution of base programs and their benefits, (b) identifying for new funding only a few, select, new research initiatives of widest national concern, (c) choosing funding mechanisms that give greater visibility to accomplishments, and (d) selecting from tangential federal research grant programs research areas that might contribute to agricultural research.

With regard to using existing resources more effectively, approaches center on (a) wider experimenting with non-traditional program management options (b) reexamining and redefining goals, philosophy, and organization of experiment stations, resident instruction colleges, and extension services, (c) seeking shorter term, more flexible methods of involving scientists outside the station in selected station activities, and (d) exploring additional ways in which state stations may work together to share resources and responsibilities.

9. In a recent study by Dr. Lipman-Blumen, it was found that agricultural research, perhaps more than other areas of government-supported research, is subject to political influences. Specifically, such things as priority setting, laboratory closings or staffing are addressed by the Committees of the Congress. Without necessarily getting into specifics, would you comment in more general, philosophical terms on the advantages and disadvantages to a research program of such close interaction with the political system?

Close interaction with the political system has been a hallmark of agricultural research in most states and in the Congress.

At the state level, in general, those experiment stations prohibited from representing agricultural research needs before the legislature receive perceptibly smaller appropriations than those that present their needs. Generally, state legislators involved in agricultural research appropriations or oversight seek to keep research programs on target, responsive, and cost effective. They expect promises to be fulfilled later by accomplishments. Most have sufficient interest to welcome both applied and basic investigations so long as they seem in balance. Most are true friends of research. Occasionally, a legislator or a governor may overstep and interject themselves in management decisions. Occasionally, powerful interest groups may cause the legislature to appropriate funds for research on topics not of great priority to station administrators. Occasionally, requests to fund certain research investigations, particularly in the social sciences or home economics, are not received with enthusiasm or are denied by the legislature. Nonetheless most

station directors prize opportunities to interact with legislators or the governor.

Members of the Congress deal with much larger, more complex, often intractable issues than state legislators. They are more remote from everyday problems of their constituency. Nonetheless, they, too, are genuinely interested in agricultural research and its accomplishments. Congressional inquiry into priority setting, laboratory closings or staffing is an important element in keeping research programs geared to needs. Some members respond directly to requests from their constituents by seeking earmarked funds or tight control. Others are content to communicate with federal or state research administrators about such requests. Each member seems to have a finely tuned sense of the appropriate; even those committed to earmarking seem to confine themselves to symbolic responses.

As a matter of personal preference, I prefer legislators or members of Congress who take an active interest in research, who ask tough questions, who ask what taxpayers got for their money, and who, when convinced of the merits of research, will support it vigorously.

10. On Page 7 of your prepared testimony, you stated that new discoveries in agricultural research are adopted quickly and there is little unutilized technology in reserve. What is special about agricultural research that leads to such rapid technology transfer?

Most agricultural scientists are strongly mission-oriented; their administrators and extension colleagues are even more so. All are fascinated with attempting to fit new discoveries into current practices. They interact frequently enough with research users to know that users also have great interest and will respond rapidly. Indeed, on certain issues, users often will phone investigators to get the latest on their research.

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

FRIDAY, OCTOBER 4, 1985

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
TASK FORCE ON SCIENCE POLICY,
Washington, DC.

The task force met, pursuant to call, at 9:30 a.m., in room 2318, Rayburn House Office Building, Hon. Don Fuqua (chairman of the task force) presiding.

Mr. FUQUA. This is the third day of 6 days of hearings on the topic of Science in the Mission Agencies and Federal Laboratories.

Today we will be exploring the overall policies that apply to mission agencies in relationship with research performers including Federal laboratories, nonprofit institutions and industry.

And our first panel will examine these policies in relationship from the point of view of the mission agencies, including Dr. Alvin Trivelpiece, Director of Office of Energy Research from the Department of Energy; Dr. Orville G. Bentley, Assistant Secretary of Science and Education, Department of Agriculture; and Dr. Frank B. McDonald, Chief Scientist of the National Aeronautics and Space Administration.

Dr. Trivelpiece, we will begin with you and hear from you all, and when all of you have completed, we will have some questions at that time.

PANEL 1: MISSION AGENCIES AND EXTRAMURAL RESEARCH

STATEMENT OF DR. ALVIN W. TRIVELPIECE, DIRECTOR, OFFICE OF ENERGY RESEARCH, U.S. DEPARTMENT OF ENERGY, WASHINGTON, DC

Dr. TRIVELPIECE. Thank you, Mr. Chairman.

This is the first time I have had the opportunity to appear before the task force, and I appreciate the opportunity.

The questions which you are raising and the material which you have sent out are very important questions, and they are relevant for the Nation to try to seek answers to them. Some of the questions are relatively easy to answer and easy to handle, and some of them involve kind of imponderable issues that involve the future course of the Nation. I would like to applaud the efforts of the task force to take on these questions, and I think you are doing a good job of it.

You certainly are well aware from my past testimony how important I believe science and technology are to the economic health and well-being of the Nation and to try to get these things supported well. DOE has played an important role in this collection of activities, and I believe will continue to play it in the future. It is a leader in energy and science and in national security.

Just a couple of brief statements. There are facilities in the Department of Energy, 57 of them, and 129,000 employees that are all GOCO Laboratory employees. The Department's budget, in terms of cash flow, is about $24 billion, and the reason that our appropriation is only $13 billion is we are in several businesses—that if we were an oil company, I think in terms of profits we would be one of the Seven Sisters. The revenue that flows through the Treasury is rather substantial, but the net to zero adds something like $12 to $13 billion to the cash flow of the Department.

The $13 billion appropriation is what I want to focus on for a moment. Of that, $10.9 billion goes to facilities, collectively—all the 57 facilities—and of that, $3.7 billion goes to the nine major multiprogram laboratories: Livermore, Los Alamos, Oak Ridge, Argonne, and so on. These laboratories then are involved in many different activities. We also are involved in supporting activities that are important to the Nation through the university channels that flow directly from the Department.

There is something like $345 million that goes to contracts at academic institutions. If you look at the amount that goes from the Department to laboratories to academic institutions, then there is another 300 some odd million that goes into that. If you then take into account the amount of funding that goes to places like Fermi Laboratory being distributed across the 100 universities or so on that it serves, you would roughly double that other sum. So, it would be somewhere in excess of $1 billion of Department funds that goes into the academic enterprise in the United States.

In the science area, of course, the Department is involved in the support of the high energy physics, nuclear physics, and many areas of biology and nuclear medicine research, as well as areas in such things as materials and chemistry and biology, quite a broad span of basic research. The Department's activities do span the complete spectrum from the very pure and esoteric pursuit of quarks in the nucleus of the atom to applied technology in the form of photocells and biomass.

Some 6,000 graduate students receive their support through this, and there are a number of other activities that involve the use of the laboratories for training of undergraduates and graduate students through the cooperative program.

I would like to call attention to just one thing that is mentioned in my prepared testimony which I assume is going to be made available for the record.

Mr. FUQUA. Yes. I failed to mention that at the beginning, but we will make all of the prepared statements in their entirety part of the record, and any summary of that would be in addition to that.

Dr. TRIVELPIECE. As a result of some encouragement from the Secretary who, I think, had been encouraged by the President to see what we could do in the way of additional things for high

school students this year, the Department had several programs, one of which was that we ask the Governors of each of the States to locate within their State the smartest student in mathmatics, physics and computer sciences. And then the Department arranged to take these 52 students, 1 also from the District of Columbia and Puerto Rico, out to Lawrence Livermore Laboratory and have them run on the Cray supercomputer there for 2 weeks and have lectures by leading scientists in the various areas.

I had the good fortune to go out and meet many of these youngsters who are in high school. It is a little terrifying to have a 14-year-old explaining to you some of the esoteric aspects of pure mathmatics worrying about whether or not he has a future and job security if he pursued this particular line of research. I tried to assure him he was probably eminently employable. The only problem, I think, is we have had to change all the passwords we gave them for their summer participationist activity.

The Department likes to believe that what it does, it tries to do with some degree of pursuit of excellence, and one of the statistics that we like to quote is that there are some 41 Nobel laureates of the United States who have been involved with the Department in doing their research, many of whom are still involved with them.

There are many things that your questions raise. Today, I will be happy to answer questions after my colleagues here on the panel have had their opportunity to testify.

Thank you, Mr. Chairman.

[The prepared statement of Dr. Trivelpiece follows:]

Statement of Alvin W. Trivelpiece

Director

Office of Energy Research

Department of Energy

before the

Science Policy Task Force

of the

House Science and Technology Committee

October 4, 1985

Mr. Chairman and Members of the Task Force on Science Policy:

I am pleased to appear before you today to discuss the Department of Energy's (DOE's) policies that apply to basic and applied research and, in particular, the Department's relationships with the Federal laboratories, universities, and industrial organizations that carry out that research.

Let me begin by saying that the Department has broad mission goals that are highly science and technology intensive. DOE mission areas, very broadly stated, are energy, defense, and science. In its role of supporting research and development, the Department aims to advance the frontiers of basic scientific and technical knowledge and to support the development of new and alternative energy resources through scientific and technical research for further development and utilization by the private sector. While the missions of the Department are now clear and relatively stable, the interrelationships of the institutions that fund and carry out research in support of them, are continually evolving and changing. The dynamic nature of the research and the institutions that perform it is the one constant in our relationships with the three major R&D performing sectors--private industry, the Federal laboratories, and colleges and universities.

In considering the interrelationships among DOE and its research performers, which I will discuss in more detail in the following pages, it is important to take note of the importance of the research itself. Over the years, the technology and knowledge generated in DOE's mission areas have become a major part of the U.S. technology base and have been reapplied by industry for use in many commercial processes and products. Nuclear power, nuclear medicine, radiation processing, ion implantation, materials advances, fluidized bed coal

combustion, and supercomputers are but a few of the extensive applications of technology and knowledge that have occurred as a result of R&D sponsored by the Department.

These very real applications should not obscure the fact that basic research is long-term in nature and often contributes no immediate, measurable benefit. However, these research results add incrementally to our knowledge base. For example, bone marrow transplantation work undertaken very early in what is now DOE's Biological and Environmental Research program ultimately provided the essential underpinnings for the current state-of-the-art in organ transplant work. The result of research in any of the basic science areas may be a product, an answer to a specific question, or simply a reduction in uncertainty. The results of our scientific research, taken as a whole, comprise nothing less than an investment in our national security, economic strength, and national well-being.

Each research performer--the laboratories, universities, and private industry--have important and distinct responsibilities in assisting us to maintain a strong scientific and technological base in all energy areas. The principal criterion used by the Department in selecting the appropriate performer to carry out research is scientific and technical excellence regardless of the location and type of performer. The competitive process provides us with the assurance that the best research will be supported.

BACKGROUND

The evolution in the relationships with our research performers began in the 1940's when the Manhattan Project was expanded into the Atomic Energy Commission. In those early days, the majority of the Commission-sponsored research was done by a complex of national laboratories through a unique contractual partnership with universities and industry. Several of the Government-owned, contractor-operated laboratories were multidisciplinary in nature because of the need for expertise in virtually all of the sciences as they related not only to the Manhattan Project but to the later inclusion of nuclear power research as a laboratory mission. The multidisciplinary nature of the laboratories' missions expanded even more with the establishment of the Energy Research and Development Administration. Today, the DOE laboratory complex comprises the largest group of Government-owned, contractor-operated facilities in the U.S. and, indeed, in the world. In addition to their multidisciplinary capabilities, all of the multiprogram laboratories have extensive research facilities and the ability to assemble project or program teams on a rapid-turnaround basis. Taken together, the expertise, equipment, facilities, and capabilities at the national laboratories represent a true national research and development resource.

These national laboratories do not exist in isolation. They have a long history of relationships with the university and industry communities through a variety of mechanisms. Some laboratories have particularly close relationships with universities because their operating contractor is a university or a university consortium. In almost all laboratories, large numbers of university faculty and students (sometimes up to 20% of the full-

time equivalent staff) work for extended periods. It is the policy of the Department to make its laboratories and facilities available to qualified scientists who can make the best use of these capabilities. This includes major DOE facilities with associated equipment and instruments, which are officially designated as either national research facilities (e.g., Stanford Linear Accelerator Center and the Fermi National Accelerator Laboratory) or user facilities at one of the major multiprogram laboratories. The interaction of laboratory and university staffs at these facilities brings together some of the best scientific minds in the Country in an effort that not only produces good science but helps to train students who will carry their new knowledge and experience into future careers in both the Government and the private sector.

Within this general policy guidance, there is continued emphasis on university involvement, both from a research and from a training perspective. As noted, university researchers are essential participants in all DOE-sponsored R&D. In FY 1985 alone, direct funding for universities totalled approximately $345 million. In part, these funds supported some 3000 to 3500 graduate students working on university projects as well as an additional 2000 to 3000 graduate students supported indirectly through the laboratories. We estimate that an additional $300-350 million was provided in FY 1985 in indirect support through the laboratories for university related research. This includes the use of laboratory research facilities and instrumentation by faculty and students and summer research participation of university scientists at the laboratories. Several of our laboratories have particularly close ties with nearby universities. For example, Oak Ridge National Laboratory and the University of Tennessee have collaborated on the development of a joint Distinguished Scientist Program. Similar cooperative efforts are in place

between the University of New Mexico and our Sandia and Los Alamos Laboratories and between the Pacific Northwest Laboratory and regional universities and colleges.

Laboratory relationships with industry also have been significant. The history of the development of the nuclear power industry is but one example of the fruits of such relationships. Currently, relationships generally take the form of subcontracting with industry for technical and engineering analyses and component and hardware development, and participation by industrial scientists on DOE laboratory advisory and peer review groups. Industry personnel are increasingly working side by side with laboratory staff on problems of mutual interest and utilizing DOE user research facilities. Two facilities funded by ~~the Department~~'s Office of Energy Research are among those offering ever-increasing access to industrial researchers. They are the Combustion Research Facility at Sandia-Livermore where the focus is on laser diagnostics of combustion systems and the National Synchrotron Light Source (NSLS) at Brookhaven National Laboratory. The NSLS is a valuable research tool serving the physics, materials, chemical, and biological research communities. The NSLS operates 24 hours a day, seven days a week and attracts both industrial and university researchers.

Industrial users have spent in excess of $7 million dollars at NSLS to build special beam lines for special research purposes. IBM, for example, has built a special beam line to conduct research on x-ray lithography, a process of great potential for the production of computer chips a fraction of their current size. Furthermore, these industry-funded beam lines are made available for a portion of the time to the general research community.

CURRENT AND FUTURE DIRECTIONS

Policy regarding the use of the major research performers--Federal laboratories, universities, and industry--has resulted over the years in a balanced approach aimed at using the best performer for a given task. Administration policy calls for increased reliance on the private sector for technological advancements of interest to the marketplace but recognizes an appropriate Federal role in long-term research in the national interest beyond what can be expected from the private sector. The Department's policy regarding support for basic and applied research is to maintain core research programs in the laboratories, particularly in situations where capital-intensive equipment is required, long-term research is entailed, or where research aimed at developing new energy technologies involves large uncertainties or important energy-related environmental factors.

DOE policy also continues to stress the importance of university research to the development of new and innovative scientific and technical concepts and to the preparation and training of students. Our commitment to training students for future careers in science and engineering also extends to the precollege level. We have sponsored a series of summer research and training institutes at the laboratories for high school science students. The most unique effort was our recent High School Supercomputing Honors Institute held this past August at Livermore and involving 52 high school students representing each state, Puerto Rico and the District of Columbia. We will be building on these

efforts in the next year as we strongly believe that the scientists and research facilities at our laboratories can play important roles in the national effort to strengthen the science and mathematics programs in our secondary schools.

Both the universities and the laboratories are key links in the transfer of technology into the private sector. This transfer of knowledge and, ultimately, technology into use in the private sector where it can contribute to the Nation's economic health and well-being and national security is our overriding goal. The DOE R&D Laboratory Technology Transfer Program, managed by the Office of Energy Research, was implemented in response to the Stevenson-Wydler Technology Innovation Act. The purpose of the technology transfer program is to facilitate improved use by State and local governments and the private sector of federally funded technology developments to strengthen the U.S. industrial base and competitive position in the international marketplace. The key to the transfer of technology is person-to-person interactions between our laboratory researchers and industry counterparts. As noted earlier in my testimony, we are providing increasing opportunities for industry involvement at the laboratories and have encouraged the laboratories to identify appropriate laboratory technology and inform interested firms. One recent effort in this regard was the initiation of our Laboratory Industry Technology Exchange Program. Through this program, industrial scientists are spending up to a year in a visiting research appointment at a DOE laboratory working on research of mutual interest to both the laboratory and the scientist's company. In FY 1985 12 appointments were made at 7 laboratories. The appointments are jointly funded by the laboratory and the industrial company.

In summary, DOE policy and practices are aimed at improving the laboratory management process and the accessibility of the laboratories to university and industry researchers. Specifically, the Department has established:

--an institutional planning process that will provide a continuing opportunity to reexamine laboratory missions;

--an annual laboratory appraisal process which will contribute to optimum research and management performance;

--an improved technology transfer program;

--a central Headquarters council to address broad R&D policy issues in a timely manner; and

--a new patent and work for others policy that provides the laboratories more opportunities to increase interactions with the private sector.

In addition, the Department is committed to:

--involving university scientists, as appropriate, in all energy research and development programs;

--recognizing the educational benefits of DOE-sponsored research by encouraging and providing support for student participation in research;

--encouraging interaction and collaboration in energy research among university, industrial and national laboratory groups;

--expanding opportunities for university faculty and students to utilize the special and unique facilities and equipment at the DOE laboratories; and

--streamlining pre- and post-award grants procedures to aid in decreasing the administrative burden on DOE research grant recipients and the Federal Government. (Also, we will be looking closely at the recommendations in this area from the National Academy of Sciences Government/University/Industry Roundtable.)

I believe that it is clear from the policies and trends that I have summarized that the Department fully recognizes the immense value to the Nation of the R&D programs it supports and the importance of the R&D performers who carry them out. Perhaps equally as important, we recognize the need to be responsive to changing circumstances, needs, and opportunities both from an international and a domestic perspective. In this effort, we will continue to use the advice of our research performers, our technical and policy advisory groups, and the Congress. In this context, we look forward to the results of the work being done by your Science Policy Task Force.

Mr. Chairman, that concludes my prepared statement. I have touched broadly on a few of the many important issues related to science policy and will be happy to respond to your questions in more detail.

Mr. FUQUA. Thank you very much, Dr. Trivelpiece.
Dr. Bentley.
[A biographical sketch of Dr. Bentley follows:]

DR. ORVILLE G. BENTLEY

Orville G. Bentley serves as the Nation's first Assistant Secretary for Science and Education. He was sworn in October 19, 1982, by Secretary of Agriculture John R. Block.

The South Dakota native is responsible for directing evaluating the U.S. Department of Agriculture's role in the food and agricultural sciences. Under Dr. Bentley's leadership, the mandated Joint Council on Food and Agricultural Sciences has made great strides in targeting and promoting future efforts in research in the sciences that affect the food and fiber industries. The published reports produced by various satellite committees of the Joint Council have had great impact on the agriculturally-oriented science and education communities, the agricultural industry, and other government agencies concerned with food, nutrition, chemicals, and the environment.

In response to planning activities led by Dr. Bentley, a new $20 million Biotechnology Competitive Grants Research initiative was established. Major program redirections were started by the Agricultural Research Service, Extension Service, and the National Agricultural Library. Dr. Bentley currently serves on many committees and boards, among which are the Government-University-Industry Roundtable, the Cabinet Council's Subcommittee on Biotechnology, and the Interagency Committee on Human Nutrition Research.

Dr. Bentley earned his B.S. degree from South Dakota State College in 1942, majoring in agriculture and chemistry. After serving four years in the United States Air Force, where he rose to the rank of Major, he received M.S. and Ph.D. degrees from the University of Wisconsin in 1947 and 1950, respectively. In recent years he has received Honorary Doctor of Science Degrees from both these universities, and Distinguished Service Awards from the Alumni Associations at South Dakota State University and the University of Illinois Urbana-Champaign.

STATEMENT OF DR. ORVILLE G. BENTLEY, ASSISTANT SECRETARY, SCIENCE AND EDUCATION, U.S. DEPARTMENT OF AGRICULTURE, WASHINGTON, DC

Dr. BENTLEY. Thank you.

Mr. Chairman, I am pleased today to have an opportunity to appear before the panel, and I, too, want to express appreciation for the efforts of the committee in the work you are doing on behalf of science and technology. And, of course, I need not say to you who have been involved with it the importance of this to the future of our country.

The Department of Agriculture is really facing a number of questions, and American agriculture is facing a number of questions.

But at the same time we are going through a period of great change, and during that time we think there are great opportunities for adjustment and change that will be taking place in the Nation's food and fiber system, primarily, in that science and technology will have an important role in this question.

A better perspective—it is appropriate to note that we are faced with a number of paradoxes. One is that some people feel that the success of agricultural science and research is contributing to the agricultural problems, and it is true that farmers and ranchers have used technology and resources to increase the yields of crops and livestock, but it is also appropriate to recall that just a few short years ago the major question before many people was: "Will there be enough food in the world?" And yet today we talk about commodity stockpiles and production that is exceeding market

demand, and there is a great deal of concern about production cutbacks.

But there have been—we also must remember there have been—a series of major changes taking place in production agriculture, and we must not overlook the fact that production agriculture is important because we are thinking in terms of food and fiber needs of this country and for the world markets, and therefore, we have to continue to give a great deal of emphasis to this area.

We also are concerned, or must note, that there is a change in the basic justification for research that is most appropriate for the times. In other words, if we are talking about a more market-driven agriculture, we have to think in terms of productivity and utilize every opportunity that is available to us to reduce costs, to enhance the quality of the products that are produced, and thereby make it possible for farmers and ranchers to produce effectively and profitably in today's market situation and probably the way it is in the future.

It is also important to remember that, when we think in terms of longer term goals and objectives, that farmers have immediate needs, and one can refer to the old statement that says—that goes about like this—that a farmer talking about long-term needs with a researcher. The farmer reminds the researcher that: "Bugs are eating my crop right now, and I need action, and I need attention to problems immediately."

So, this is the general framework in which we are working, and we are thinking about the future of American agriculture and industry, and I want now to refer to some comments related to science and technology as a part of your oversight hearings.

The agricultural science policies are all too frequently based upon reactive strategies, maintaining of our ability to divert from a charted course or undertake special mission needs that are brought about through immediate problems. To meet the challenges which face agriculture, the public system has worked together in the long-term development process as a basis of resource allocation. We do have a course of action charted. We do have priorities.

You have asked in your questions who sets the priorities and what criteria are used. There are two distinct levels of research programs that USDA, the in-house or Intermural Research Program which is conducted through the Agriculture Research Service, and the Cooperative Research Program which is coordinated by the Cooperative State Research Service. The CSR's program operates primarily through the 1862 and the 1890 land-grant institutions, and that includes Tuskegee University as well. These State universities, with priorities in the final analysis, determine the level of allocations and programs. However, there is a joint effort in the priority-setting process.

As an example of this dialogue, the needs assessment was conducted by the Joint Council on Food and Agriculture Sciences. I have submitted a copy of the report to the committee. I will just merely hold this one up to call attention to it.

The Joint Council is the organization which coordinates research activities in food and agriculture sciences. The National Agriculture Research Committee, the National Extention Committee and the National Higher Education Committee, as well as the USDA

agencies, such as Forest Service and Economic Research Service, contribute to the priority-setting process. The recommendations of the Joint Council are then forwarded to the Secretary of Agriculture. They are also made available to the heads of the non-Federal partners in the Agriculture Research System.

Again, I have provided the members of the task force with a copy of the current report of the Joint Council which details the fiscal year 1987 priorities for research, extension, and higher education, and I will call attention to this report as well.

As Assistant Secretary, I have accepted these reports and have directed the agencies under my jurisdiction to utilize them in setting individual agency priorities. These are: one, increased agricultural profitability through management; improve water quality and management; expand biotechnology efforts on plants, animals, and microbes; develop necessary scientific and professional human capital; and five, to improve human nutrition and understanding of diet, health relationships.

These—behind each of these reports are detailed statements concerning them, but I will not mention those in our conversations this morning.

Within our agencies and in the Competitive Grants Program of the USDA, this list of priorities is given serious consideration as we determine project funding and based upon specific recommendations from peer reviewers.

We have a number of advisory boards in each of these areas. The largest independent advisory board is the Users Advisory Board, which differs from the Joint Council in that it is composed of users of the agricultural sciences. These two organizations have joint meetings and do coordinate many of their activities. The individual advisory boards do have their respective priorities, and I make a concerted effort to consider their recommendations in individual areas.

The USDA fully recognizes the responsibilities to other Federal agencies, and I believe Dr. Kinney, yesterday in his remarks, made reference to these relationships as they affect his particular Agency, the Agriculture Research Service.

I want to take a moment to discuss the role of the Office of Science and Technical Policy and the Federal Coordinating Council on Science, Engineering and Technology [FCCSET].

Dr. Keyworth and his staff at OSTP have been highly supportive through policy guidelines for Federal science and education programs as they relate to agriculture.

Also, within the Federal Government, I confer with the administrators of FDA on matters relating to nutrition and biotechnology, and it also calls for frequent contacts with the EPA on agricultural chemical issues and the Department of Health and Human Services on nutrition research priorities.

Those of us in the Federal sector do try to attempt to coordinate our activities, and we look to OSTP to assist us in that particular effort. One of the questions sent to me by the committee had to do with crash programs and their impact on research. In agriculture, we do use crash projects, so to speak. Within the past year we have had to react to outbreaks of citrus canker in Florida, to withdrawal of ethylene dibromide as a fumigant, to an outbreak of avian flu in

poultry and the misuse of the chemical aldicarb which resulted in serious economic harm to the Nation's watermelon producers. Such problems do drain resources, but both the Office of Management and Budget (OMB) and the Congress have been responsible in providing funds when we need to deal with crash program requirements.

You have raised a question about relating to the role of the Department of Defense in basic research and the optimum balance between civilian and military research. In the interest of time, let me just summarize by saying we do have some cooperative relationships, and I have detailed those in my testimony, but at the current moment there is approximately $900,000 worth of research that is carried out under a memorandum of agreement. A copy of a statement relative to these programs has been provided to the committee, and I will hold it up to identify it for this purpose. The kinds of research covered have to do with nutrition, disease and insect control, wood preservation, protective systems for military subsistence in fabrics and food stuff fumigants. These, again, have been referred to in the memorandum.

With regard to our relationships with extramural research performers at USDA, the primary responsibility for such relationships is delegated to the Cooperative State Research Service and the administrator of that agency, Dr. Pat Jordan has provided you with detailed information concerning these activities.

It is appropriate to note here from the time of Abraham Lincoln this Nation has recognized the talents and the abilities of our colleges and universities, and today, with the advent of biotechnology, we are experiencing a reaffirmation in the increased intensity in this particular area.

Turning now to biotechnology, the USDA initiative in the last year in the Competitive Grants Program was aimed at exploiting the scientific opportunities for agriculture at all eligible institutions and laboratories that have the capacity to perform research on agriculturally related problems. This competitive program which was supported by the Office of Science and Technology Policy has generated a great deal of interest throughout the country. In recent months we have proposed revisions, for example, of the Research Facilities Acts which will allow institutions—land grant and non-land grant universities—to compete for funds on a matching basis for the acquisition of new facilities and equipment, and this is aimed at strengthening the capacity of our country to meet these new opportunities and challenges.

Our cooperative relationship with the private sector is also receiving a great deal of attention. Dr. Kinney has described ARS's Technology Transfer Program, and I have briefly cited just a couple of examples of such cooperative effort. Last March, ARS executed an agreement with GENEX to participate in the development of a vaccine for coccidiosis, a poultry disease. ARS is presently proposing to solicit at this time on a private basis, funds to develop a similar vaccine for trichinosis in swine.

Mr. Chairman, there is one area of great challenge to the agriculture research system. It is in the area of our relationship with the private sector. Historically, the private sector has been reluctant to exchange basic research information about the Government

simply because the Government could not guarantee that the product development, as a result of such research, would not be in, quote, the public domain.

Conditions are changing. Today, we can issue exclusive licenses to private sector companies to develop and market products which have been invented by Government scientists.

There are several pieces of legislation proposed which would allow Government laboratories to enter into private partnerships with private sector firms and institutions. We would welcome expansion of this opportunity, as we believe such relationships would be mutually beneficial. In this regard, we are working with Dr. Bruce Merrifield, the Assistant Secretary of Commerce for Productivity, Technc logy and Innovation.

As to the relationshp of the USDA to science and engineering infrastructure, you pose a number of important and relevent questions.

You have asked about the availability of qualified scientific and technical personnel to meet present and projected needs. It is certainly no secret that the number of post-doctoral students in agriculture has been declining. To change that trend, we have sponsored a Pre-Doctoral Grant Program aimed at attracting outstanding science-oriented students to pursue advanced degrees in food and agricultural sciences. This is a modest program and one which may have to be accelerated unless the present trend is reversed. There is growing competition for agricultural scientists. In the USDA, we have a number of incentive programs for our scientists: Bonus payments for outstanding work and modest payment for product patents. We have established a special employment catagory to employ a limited number of scientists on a short-term basis at the post-doctorate level. We will have to become even more innovative in the future if we are to remain competitive for personnel.

I would be remiss if I did not mention the important role which is being played by our historically black institutions in training future scientists. The 1890 institutions, Tuskegee University and the University of the District of Columbia, are all partners in the Federal system, and we have earmarked funds for Student Development Programs at these institutions.

A large network of research institutions in the public sector became necessary several years ago to develop and refine the capability of providing an inventory of products and research planning. The Current Research Information System, commonly referred to as CRIS, provides the on-line capability. This system allows specific searches by title, project, subject, and geographic area. I have here—I have a sample copy of the CRIS research reports. This happens to be a listing of all remote sensing projects, and I will give you an idea of the system and its capabilities, and here again is an example of the printout in this particular area.

The decisions of regulatory agencies impact farmers and ranchers. Decisions by the EPA and the protection of EPA often require technical responses from USDA. An example—as an example—USDA performs benefit analysis on those agricultural chemicals which are under special review status by EPA. These reviews are designed to provide information to EPA which it can use in making a final determination as to the fate of a special chemical. If, for in-

stance, a chemical is known to have adverse impacts on the environment, is there a suitable alternative? Will the withdrawal of the chemical cause undue economic hardship on the agricultural community? Are there alternatives to outright withdrawal, such as the Pesticide Applicator Program, specific use allowance and such?

Such studies are best done by USDA because we have the information network needed to obtain such data. In all instances where the USDA research is produced for regulatory agencies, we do attempt to issue results in a form that can be readily translated by the regulators. Research science often interacts directly with representatives from the regulatory agencies.

The final subject I was asked to comment on briefly involved Federal laboratories. Dr. Kinney, in his presentation on ARS yesterday, gave you an overall view as to the organization and the assignment of work in ARS laboratories. We are well pleased with the relationship which ARS has had in working with universities, including the sharing of laboratory facilities and personnel. The same general comments can be made for the laboratories administered by the Forest Service. One of the objectives I have, is to see an expansion and continuation and strengthening of these relationships over the years ahead.

The last question which you posed, deals with the policy towards establishment of new Federal laboratories and the reorientation of existing facilities. We must maintain our position as a world leader in scientific research, and this means we must devote our attention to program improvements rather than construction projects at this time.

To repeat, we are in an era of dynamic development in the agricultural sciences. There is a sense of excitement and high expectation in the research community that is shared by the leadership in the USDA. I am fully confident that the joint Federal-State system is up to the challenge if we can support them adequately in the years ahead.

I appreciate the opportunity to meet with you and make this presentation.

[The prepared statement of Dr. Bentley follows:]

STATEMENT OF

DR. ORVILLE G. BENTLEY

ASSISTANT SECRETARY

SCIENCE AND EDUCATION

U.S. DEPARTMENT OF AGRICULTURE

BEFORE THE

TASK FORCE ON SCIENCE POLICY

OF THE

COMMITTEE ON SCIENCE AND TECHNOLOGY

U.S. HOUSE OF REPRESENTATIVES

OCTOBER 4, 1985

MR. CHAIRMAN AND MEMBERS OF THE TASK FORCE ON SCIENCE POLICY, I WELCOME THIS OPPORTUNITY TO APPEAR BEFORE YOU TODAY TO DISCUSS THE U.S. DEPARTMENT OF AGRICULTURE'S RESEARCH PROGRAMS. THIS IS A MOST CRITICAL TIME FOR AMERICAN AGRICULTURE. THERE ARE OPPORTUNITIES FOR CHANGE AND ADJUSTMENTS. WE MUST PURSUE THESE OPPORTUNITIES IN SEARCH OF CONSTRUCTIVE CHANGES FOR THE NATION'S FOOD AND FIBER PRODUCERS AND THE ALLIED INFRASTRUCTURE THAT FORMS THE SYSTEM.

THERE ARE THOSE WHO MIGHT SUGGEST THAT TODAY'S PROBLEMS IN AGRICULTURE COULD BE BLAMED IN PART ON THE SUCCESSES OF AGRICULTURAL RESEARCH. FARMERS AND RANCHERS HAVE USED TECHNOLOGY AND RESOURCE MANAGEMENT SKILLS TO INCREASE YIELDS IN CROPS AND LIVESTOCK PRODUCTION. JUST A FEW SHORT YEARS AGO, THE QUESTION WAS "WILL THERE BE ENOUGH FOOD?" BUT TODAY, COMMODITY STOCKPILES ARE OVERFLOWING AND THERE ARE PROGRAMS TO ENCOURAGE PRODUCTION CUTBACKS.

IN JUST A FEW SHORT DECADES REMARKABLE AND FUNDAMENTAL CHANGES HAVE OCCURRED IN AGRICULTURE, AND THAT INCLUDES AGRICULTURAL SCIENCE. PRODUCTION AGRICULTURE IS IMPORTANT. WE MUST ALWAYS MAINTAIN THE ABILITY TO MEET MARKET DEMANDS -- BUT EQUALLY IMPORTANT ARE PRODUCTION EFFICIENCY, MARKETING, AND UTILIZATION. WE ARE PRODUCING FAR MORE FOOD AND FIBER THAN CAN BE UTILIZED IN TODAY'S MARKETPLACE. AND, INCREASED COMPETITION IN WORLD MARKETS, COUPLED WITH OTHER ECONOMIC FACTORS, HAS BROUGHT ABOUT A DECREASE IN EXPORT SALES OF AGRICULTURAL PRODUCTS.

WE HEAR THE EXPRESSION "MARKET DRIVEN AGRICULTURE" FREQUENTLY. LIKEWISE, AGRICULTURAL SCIENCE IS BECOMING MORE MARKET DRIVEN. PROFITABILITY IS BEGINNING TO PARALLEL PRODUCTIVITY AS A PRIORITY, THEREFORE IT IS NECESSARY TO IDENTIFY TECHNOLOGIES THAT IMPROVE PRODUCTIVITY THROUGH COST REDUCTIONS, ENHANCE PRODUCE QUALITY, AND LESSEN THE ADVERSE EFFECTS OF PESTS AND HARSH ENVIRONMENTS.

AND, THE NEW TECHNOLOGIES ARE COMING ON LINE AT A MOST OPPORTUNE TIME. I WILL TALK WITH YOU IN A FEW MINUTES ABOUT OUR NEW THRUSTS IN BIOTECHNOLOGY AND GENETIC ENGINEERING. BUT, BEFORE I GET TO THAT, I AM REMINDED OF THE OLD STORY ABOUT THE RESEARCHER WHO WAS TELLING THE FARMER ABOUT THE WONDERFUL THINGS SCIENCE WAS GOING TO DO FOR AGRICULTURE IN THE FUTURE. THE FARMER INTERRUPTED HIM AND SAID, "THAT'S GOOD, BUT THE BUGS ARE EATING MY CROP RIGHT NOW."

MR. CHAIRMAN, WE DO HAVE IMMEDIATE PROBLEMS EATING AT THE VERY HEART OF AMERICAN AGRICULTURE. IT IS A PROBLEM WHICH MUST HAVE OUR IMMEDIATE ATTENTION. NOT ONLY ARE OUR FARMERS AND RANCHERS CONFRONTED WITH ECONOMIC PROBLEMS, BUT THEY ARE BESET WITH WHAT MIGHT BEST BE DESCRIBED AS AGRICULTURAL ENVIRONMENTAL POLICY PROBLEMS - PARTICULARLY IN THE AREA OF AGRICULTURAL CHEMICALS AND LAND USE.

IT IS IMPORTANT FOR THIS TASK FORCE TO UNDERSTAND THAT THE MAIN THRUST OF OUR ACTIVITIES IS DIRECTED SQUARELY AT ADDRESSING THOSE ISSUES WHICH ARE IMPERILING NOT ONLY TODAY'S AGRICULTURE -- BUT THE FUTURE OF THE AMERICAN AGRICULTURAL INDUSTRY.

AGRICULTURAL SCIENCE POLICIES ARE FREQUENTLY BASED UPON REACTIVE STRATEGIES -- MAINTAINING THE ABILITY TO DIVERT FROM A CHARTED COURSE TO UNDERTAKE THOSE SPECIAL MISSIONS NECESSARY TO RESOLVE IMMEDIATE PROBLEMS. TO MEET THE CHALLENGES WHICH FACE AGRICULTURE, THE PUBLIC SYSTEM HAS WORKED TOGETHER IN PROGRAM DEVELOPMENT AND RESOURCE ALLOCATION. WE DO HAVE A COURSE OF ACTION CHARTED. WE DO HAVE PRIORITIES.

YOU ASKED "WHO SETS THE PRIORITIES AND WHAT CRITERIA ARE USED?" THERE ARE TWO DISTINCT LEVELS OF RESEARCH PROGRAMS AT USDA -- THE IN-HOUSE RESEARCH WHICH IS CONDUCTED BY THE AGRICULTURAL RESEARCH SERVICE -- AND THE COOPERATIVE RESEARCH PROGRAM WHICH IS COORDINATED BY THE COOPERATIVE STATE RESEARCH SERVICE. THE CSRS PROGRAM OPERATES PRIMARILY THROUGH THE 1862 AND 1890 LAND GRANT INSTITUTIONS -- AS WELL AS AT TUSKEGEE UNIVERSITY. THESE ARE STATE INSTITUTIONS -- WITH PRIORITIES IN THE FINAL ANALYSIS BEING DETERMINED AT THAT LEVEL.

HOWEVER, THERE IS A JOINT EFFORT IN THE PRIORITY-SETTING PROCESS. THE JOINT COUNCIL ON FOOD AND AGRICULTURAL SCIENCES IS THE ORGANIZATION WHICH COORDINATES RESEARCH ACTIVITIES IN THE FOOD AND AGRICULTURAL SCIENCES. THE NATIONAL AGRICULTURAL RESEARCH COMMITTEE, THE NATIONAL EXTENSION COMMITTEE, AND THE NATIONAL HIGHER EDUCATION COMMITTEE, AS WELL AS USDA AGENCIES SUCH AS THE FOREST SERVICE AND ECONOMIC RESEARCH SERVICE, CONTRIBUTE TO THE PRIORITY- SETTING PROCESS. THE RECOMMENDATIONS OF THE JOINT COUNCIL ARE THEN FORWARDED TO THE SECRETARY OF AGRICULTURE. THEY ARE ALSO MADE AVAILABLE TO THE HEADS OF THE NON-FEDERAL PARTNERS IN THE AGRICULTURAL RESEARCH SYSTEM. I HAVE PROVIDED EACH MEMBER OF THIS TASK FORCE WITH A COPY OF THE CURRENT REPORT OF THE JOINT COUNCIL WHICH DETAILS FY 1987 PRIORITIES FOR RESEARCH, EXTENSION, AND HIGHER EDUCATION.

57-279 O - 87 - 11

AS THE ASSISTANT SECRETARY FOR SCIENCE AND EDUCATION, I HAVE ACCEPTED THIS REPORT AND HAVE DIRECTED THE AGENCIES UNDER MY JURISDICTION TO UTILIZE THIS REPORT IN SETTING INDIVIDUAL AGENCY PRIORITIES. THOSE PRIORITIES ARE:

1. INCREASE AGRICULTURAL PROFITABILITY THROUGH MANAGEMENT.
2. IMPROVE WATER QUALITY AND MANAGEMENT.
3. EXPAND BIOTECHNOLOGY EFFORTS ON PLANTS, ANIMALS, AND MICROBES.
4. DEVELOP NECESSARY SCIENTIFIC AND PROFESSIONAL HUMAN CAPITAL.
5. IMPROVE HUMAN NUTRITION AND UNDERSTANDING OF DIET/HEALTH RELATIONSHIPS.

IN THE REPORT, YOU WILL FIND THE DETAILED DESCRIPTIONS OF EACH OF THESE FIVE PRIORITIES.

WITHIN OUR OWN AGENCIES, AND IN THE COMPETITIVE GRANTS PROGRAMS OF USDA, THIS LIST OF PRIORITIES IS GIVEN SERIOUS CONSIDERATION AS WE DETERMINE PROJECT FUNDING -- BASED UPON SPECIFIC RECOMMENDATIONS OF PEER REVIEWERS.

WE HAVE A NUMBER OF ADVISORY BOARDS, EACH WITH A SPECIFIC MISSION. THE LARGEST INDEPENDENT ADVISORY BOARD IS THE USERS ADVISORY BOARD -- WHICH DIFFERS FROM THE JOINT COUNCIL IN THAT IT IS COMPOSED OF USERS OF THE AGRICULTURAL SCIENCES. THESE TWO ORGANIZATIONS DO HAVE JOINT MEETINGS AND DO COORDINATE MANY OF THEIR ACTIVITIES. THE INDIVIDUAL ADVISORY BOARDS DO HAVE THEIR RESPECTIVE PRIORITIES AND I MAKE A CONCERTED EFFORT TO CONSIDER THEIR RECOMMENDATIONS IN INDIVIDUAL PROGRAM AREAS.

USDA FULLY RECOGNIZES ITS RESPONSIBILITIES TO THE OTHER FEDERAL AGENCIES -- AND I BELIEVE DR. KINNEY, THE ADMINISTRATOR OF THE AGRICULTURAL RESEARCH SERVICE, HAS TOUCHED UPON THE RELATIONSHIP HIS AGENCY HAS WITH MANY OF THESE AGENCIES. I WANT TO TAKE JUST A MOMENT ABOUT THE ROLE OF THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY (OSTP), AND THE FEDERAL COORDINATING COUNCIL ON SCIENCE, ENGINEERING, AND TECHNOLOGY (FCCSET).

DR. GEORGE KEYWORTH AND THE STAFF OF OSTP HAVE BEEN OF TREMENDOUS HELP IN PROVIDING POLICY GUIDANCE FOR FEDERAL SCIENCE AND EDUCATION PROGRAMS. THE CONGRESS AND THE AMERICAN PEOPLE BECOME CONCERNED OVER THE POSSIBILITY OF WASTEFUL DUPLICATION IN SCIENCE PROGRAMS. YET, AS I INTERACT WITH MY COUNTERPARTS AT THE DEPARTMENT OF HEALTH AND HUMAN SERVICES, THE ENVIRONMENTAL PROTECTION AGENCY, AND OTHER FEDERAL AGENCIES, I FIND LITTLE, IF ANY, OUTRIGHT DUPLICATION OF EFFORT. SINCE RESEARCH IS "PROBLEM SPECIFIC" THERE MAY BE INSTANCES WHERE TWO OR MORE AGENCIES MAY, IN FACT, BE WORKING ON A SIMILAR PROJECT. HOWEVER, BECAUSE SUCH WORK IS ALSO SITE SPECIFIC, DIFFERENT FINDINGS MAY BE OBTAINED. FOR EXAMPLE, RESEARCH INTO THE APPLICATION OF PESTICIDES ON CORN MAY BE CONDUCTED IN FLORIDA AND IN ILLINOIS. BUT BECAUSE OF THE DIFFERENT CLIMATES AND SOILS, THE PROJECTS -- ALTHOUGH IDENTICAL IN NATURE, WOULD ACTUALLY BE UNIQUE.

WITHIN THE FEDERAL GOVERNMENT, I OFTEN CONFER WITH THE ADMINISTRATOR OF THE FOOD AND DRUG ADMINISTRATION ON MATTERS RELATING TO NUTRITION AND BIOTECHNOLOGY. I FREQUENTLY INTERACT WITH THE ENVIRONMENTAL PROTECTION AGENCY ON AGRICULTURAL CHEMICAL ISSUES. THOSE OF US IN THE FEDERAL SECTOR DO COORDINATE OUR ACTIVITIES AND OSTP PLAYS A KEY ROLE IN SUCH EFFORTS.

I TURN NOW TO YOUR QUESTION RELATING TO HOW "CRASH PROGRAMS" IMPACT OUR RESEARCH ACTIVITIES. IN AGRICULTURE, WE ARE USE TO "CRASH PROJECTS." WITHIN THE PAST YEAR, WE HAVE HAD TO REACT TO AN OUTBREAK OF CITRUS CANKER IN FLORIDA, TO A WITHDRAWAL OF ETHYLENE DIBROMIDE (EDB) AS A FUMIGANT, TO AN OUTBREAK OF AVIAN FLU IN POULTRY, AND THE MISUSE OF THE CHEMICAL ALDICARB WHICH RESULTED IN SERIOUS ECONOMIC HARM TO THE NATION'S WATERMELON PRODUCERS. SUCH PROJECTS DO DRAIN RESOURCES -- BUT BOTH THE OFFICE OF MANAGEMENT AND BUDGET, AND THE CONGRESS HAVE BEEN RESPONSIVE IN PROVIDING FUNDING NEEDED TO PAY FOR SUCH "CRASH PROGRAMS."

YOU HAVE RAISED A QUESTION REGARDING THE ROLE OF THE DEPARTMENT OF DEFENSE IN BASIC RESEARCH AND THE "OPTIMUM BALANCE" BETWEEN CIVILIAN AND MILITARY RESEARCH. MR. CHAIRMAN, IN 1982 A FORMAL MEMORANDUM OF UNDERSTANDING WAS EXECUTED BETWEEN USDA AND DOD. AS A RESULT OF THAT DOCUMENT, WE HAVE AN COOPERATIVE RELATIONSHIP WITH DEFENSE. DOD IS PRESENTLY FUNDING IN EXCESS OF $900,000 IN AGRICULTURAL RESEARCH THROUGH THE AGRICULTURAL RESEARCH SERVICE. ARS ALSO EXPENDS ADDITIONAL FUNDS IN SUPPORT OF DOD RESEARCH PROJECTS. THE MAIN AREAS OF MUTUAL INTEREST, AS DEFINED THROUGH THE MEMORANDUM, ARE NUTRITION RESEARCH, DISEASE AND INSECT CONTROL, WOOD PRESERVATION, PROTECTIVE SYSTEMS FOR MILITARY SUBSISTENCE AND FABRICS, AND FOODSTUFF FUMIGANTS. I HAVE SUBMITTED FOR YOUR INFORMATION AND REVIEW TWO DOCUMENTS RELATING TO THIS SUBJECT, THE FIRST IS A LETTER OF MAY 21, 1984 FROM DOD TO USDA WHICH CONTAINS DOD'S RECOMMENDATIONS FOR USDA PEST MANAGEMENT RESEARCH. THE SECOND DOCUMENT IS A COPY OF THE DOD FOOD AND NUTRITION RESEARCH AND ENGINEERING PROGRAM FOR FISCAL YEARS 1986, 87, AND 88 WHICH HAS BEEN TRANSMITTED TO USDA IN ORDER TO KEEP US FULLY ABREAST OF THEIR RESEARCH ACTIVITIES IN THESE AREAS.

WE ALSO HAVE A NUMBER OF OTHER PROJECTS IN WHICH WE ARE COOPERATIING WITH DOD. AS AN EXAMPLE, THE DEPARTMENT OF DEFENSE HAS A PROJECT TO EXAMINE THE COMMERCIAL PRODUCTION OF GUAYULE RUBBER FOR MILITARY USES SUCH AS AIRCRAFT TIRES AND TANK PADS -- BOTH OF WHICH REQUIRE NATURAL RUBBER. SINCE WE ALSO HAVE A GUAYULE RESEARCH PROGRAM UNDER THE CRITICAL AGRICULTURAL MATERIALS ACT, WE HAVE BEEN ABLE TO ASSIST DOD IN THIS PROJECT. AND, WE ARE PRESENTLY WORKING WITH THE ARMY TANK COMMAND AND TEXAS A&M UNIVERSITY TO SUPPLY THE ARMY WITH PROCESSED GUAYULE RUBBER. WE ARE INTERESTED IN GUAYULE FROM THE STANDPOINT OF IT BEING A POTENTIALLY PROFITABLE AGRICULTURAL CROP. WE ARE NOW DISCUSSING WITH DOD THE POSSIBILITY OF OUR TAKING AN EVEN MORE ACTIVE ROLE IN THIS PROJECT.

WITH REGARD TO OUR RELATIONSHIPS WITH EXTRAMURAL RESEARCH PERFORMERS. AT USDA, THE PRIMARY RESPONSIBILITY FOR SUCH RELATIONSHIPS IS DELEGATED TO THE COOPERATIVE STATE RESEARCH SERVICE, AND THE ADMINISTRATOR OF THAT AGENCY, DR. PATRICK JORDAN, HAS PROVIDED YOU WITH DETAILED INFORMATION REGARDING THIS RELATIONSHIP. FROM THE TIME OF ABRAHAM LINCOLN, THIS NATION HAS RECOGNIZED THE TALENTS AND ABILITIES OF OUR COLLEGES AND UNIVERSITIES. TODAY, WITH THE ADVENT OF BIOTECHNOLOGY, WE ARE WITNESSING AN INTENSIFICATION OF THAT INTEREST.

THE BIOTECHNOLOGY INITIATIVE OF USDA WAS AIMED AT EXPLOITING SCIENTIFIC OPPORTUNITIES FOR AGRICULTURE AT ALL ELIGIBLE INSTITUTIONS AND LABORATORIES THAT HAVE THE CAPABILITY TO PERFORM BASIC RESEARCH ON AGRICULTURE-RELATED PROBLEMS. THIS COMPETITIVE PROGRAM, WHICH WAS SUPPORTED BY THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY, HAS GENERATED A GREAT DEAL OF INTEREST THROUGHOUT THE COUNTRY. AND, IN RECENT MONTHS, WE PROPOSED REVISIONS TO THE RESEARCH FACILITIES ACT WHICH WILL ALLOW INSTITUTIONS -- LAND GRANT AND NON-LAND GRANTS -- TO COMPETE FOR FUNDS ON A MATCHING BASIS FOR THE ACQUISITION OF NEW FACILITIES AND EQUIPMENT. SHOULD CONGRESS CONCUR IN OUR REQUEST FOR REVISIONS TO THE ACT, WE INTEND TO BASE OUR FUNDING DECISIONS ON TWO FACTORS: WHETHER OR NOT THE PROPOSED FACILITY WILL BE USED IN ADDRESSING NATIONAL AND REGIONAL RESEARCH PRIORITIES, AND UPON THE FINANCIAL COMMITMENT TO THE PROJECT EXPRESSED BY THE STATE.

WE ARE ALSO CONCERNED WITH THE NEED TO UPGRADE THE PROGRAMS AND FACILITIES OF OUR NATION'S HISTORICALLY BLACK COLLEGES AND UNIVERSITIES. FOR THE PAST FOUR YEARS, IN COOPERATION WITH THE CONGRESS, $40 MILLION HAS BEEN PROVIDED TO THESE INSTITUTIONS FOR THE PURPOSE OF UPGRADING OF RESEARCH FACILITIES.

OUR COOPERATIVE RELATIONSHIP WITH THE PRIVATE SECTOR IS ALSO RECEIVING A GREAT DEAL OF ATTENTION. DR. KINNEY HAS DESCRIBED THE ARS' TECHNOLOGY TRANSFER PROGRAM AND I WILL BRIEFLY CITE JUST A COUPLE OF EXAMPLES OF SUCH COOPERATIVE EFFORTS: LAST MARCH ARS EXECUTED AN AGREEMENT WITH GENEX TO PARTICIPATE IN THE DEVELOPMENT OF A VACCINE FOR COCCIDIOSIS, A POULTRY DISEASE. AND, ARS IS PRESENTLY PREPARING TO SOLICIT ON A COMPETITIVE BASIS FOR A PRIVATE SECTOR PARTNER TO DEVELOP A SIMPLE TEST FOR TRICHINOSIS IN SWINE.

MR. CHAIRMAN, IF THERE IS ONE AREA OF GREAT CHALLENGE IN THE AGRICULTURAL RESEARCH SYSTEM, IT IS IN THE AREA OF OUR RELATIONSHIP WITH THE PRIVATE SECTOR. HISTORICALLY, THE PRIVATE SECTOR HAS BEEN RELUCTANT TO EXCHANGE BASIC RESEARCH INFORMATION WITH THE GOVERNMENT SIMPLY BECAUSE THE GOVERNMENT COULD NOT GUARANTEE THAT A PRODUCT DEVELOPED AS THE RESULT OF SUCH RESEARCH WOULD NOT BE "IN THE PUBLIC DOMAIN."

CONDITIONS ARE CHANGING -- TODAY WE CAN ISSUE EXCLUSIVE LICENSES TO PRIVATE SECTOR COMPANIES TO DEVELOP AND MARKET PRODUCTS WHICH HAVE BEEN INVENTED BY GOVERNMENT SCIENTISTS.

WE HAVE GENERAL KNOWLEDGE ABOUT PRIVATE SECTOR RESEARCH ACTIVITIES -- AND THE PRIVATE SECTOR IS GENERALLY WELL AWARE OF USDA RESEARCH. BUT THERE ARE SEVERAL PROJECTS IN THE PRIVATE SECTOR WHICH ARE AKIN TO "TOP SECRET" AND TO WHICH WE HAVE NO ACCESS. AS AN EXAMPLE OF SUCH A PROPRIETARY PROJECT, TWO FIRMS HAVE BEEN PARTICIPATING IN A PROJECT UTILIZING THE NASA SPACE SHUTTLE.

WE LEARN THROUGH THE NEWS MEDIA THAT THESE FIRMS HAVE BEEN ABLE TO CREATE USABLE QUANTITIES OF A TOP-SECRET HORMONE TO BE SEPARATED FROM A BUFFER SOLUTION -- SOMETHING WHICH IS DIFFICULT TO DO ON EARTH. THIS IS AN EXCITING DEVELOPMENT, ONE WHICH MAY HOLD GREAT PROMISE IN THE DEVELOPMENT OF DRUGS. ONE CAN SURMISE THAT THE PRIVATE SECTOR HAS MILLIONS OF DOLLARS INVESTED IN THIS PROJECT AND HAS LITTLE INTEREST IN ALLOWING COMPETITORS TO GAIN ACCESS TO IT.

THERE HAVE BEEN SEVERAL PIECES OF LEGISLATION PROPOSED WHICH WOULD ALLOW GOVERNMENT LABORATORIES TO ENTER INTO LIMITED PARTNERSHIPS WITH PRIVATE SECTOR FIRMS AND INSTITUTIONS. WE WOULD WELCOME SUCH AN OPPORTUNITY AND BELIEVE SUCH RELATIONSHIPS WOULD BE MUTUALLY BENEFICIAL. IN THIS REGARD, I HAVE WORKED CLOSELY WITH DR. BRUCE MERRIFIELD, THE ASSISTANT SECRETARY OF COMMERCE FOR PRODUCTIVITY, TECHNOLOGY AND INNOVATION.

AS TO THE RELATIONSHIP OF USDA TO THE SCIENCE AND ENGINEERING INFRASTRUCTURE, YOU POSE A NUMBER OF RELEVANT QUESTIONS.

YOU HAVE ASKED ABOUT THE AVAILABILITY OF QUALIFIED SCIENTIFIC AND TECHNICAL PERSONNEL TO MEET PRESENT AND PROJECTED NEEDS. IT IS CERTAINLY NO SECRET THAT THE NUMBER OF POST-DOCTORAL STUDENTS IN AGRICULTURE HAS BEEN DECLINING. TO CHANGE THAT TREND, WE HAVE SPONSORED A PRE-DOCTORAL GRANTS PROGRAM AIMED AT ATTRACTING OUTSTANDING SCIENCE-ORIENTED STUDENTS TO PURSUE ADVANCED DEGREES IN THE FOOD AND AGRICULTURAL SCIENCES. THIS IS A MODEST PROGRAM AND ONE WHICH MAY HAVE TO BE ACCELERATED UNLESS THE PRESENT TREND IS REVERSED. THERE IS GROWING COMPETITION FOR AGRICULTURAL SCIENTISTS. IN USDA, WE HAVE A NUMBER OF INCENTIVE PROGRAMS FOR OUR SCIENTISTS -- BONUS PAYMENTS FOR OUTSTANDING WORK, AND MODEST PAYMENTS FOR PRODUCT PATENTS. WE WILL HAVE TO BECOME EVEN MORE INNOVATIVE IN THE FUTURE IF WE ARE TO REMAIN COMPETITIVE.

I WOULD BE REMISS IF I DID NOT MENTION THE IMPORTANT ROLE WHICH IS BEING PLAYED BY OUR HISTORICALLY BLACK INSTITUTIONS IN TRAINING FUTURE SCIENTISTS. THE 1890 INSTITUTIONS, TUSKEGEE UNIVERSITY, AND THE UNIVERSITY OF THE DISTRICT OF COLUMBIA ARE ALL PARTNERS IN THE FEDERAL SYSTEM AND WE HAVE EARMARKED FUNDS FOR STUDENT DEVELOPMENT PROGRAMS AT THESE INSTITUTIONS.

WITH THE LARGE NETWORK OF RESEARCH INSTITUTIONS IN THE PUBLIC SECTOR, IT BECAME NECESSARY SEVERAL YEARS AGO TO DEVELOP AND REFINE THE CAPABILITY OF PROVIDING AN INVENTORY OF PROJECTS AND RESEARCH FINDINGS. THE CURRENT RESEARCH INFORMATION SYSTEM (CRIS) PROVIDES THAT ON-LINE CAPABILITY. THIS SYSTEM ALLOWS SPECIFIC SEARCHES BY TITLE, PROJECT, SUBJECT, AND GEOGRAPHIC AREA. I HAVE SUBMITTED TO YOU A SAMPLE COPY OF A CRIS RESEARCH REPORT. THIS ONE HAPPENS TO BE A LISTING OF ALL REMOTE SENSING PROJECTS AND IT WILL GIVE YOU A GOOD IDEA OF THE SYSTEM CAPABILITIES.

TURNING TO YOUR QUESTION RELATING TO INTERNATIONAL ISSUES, I CAN ONLY SAY THAT IN THE CONTEXT OF NATIONAL SECURITY, WE HAVE FEW CLASSIFIED PROJECTS. WE DO EXCHANGE A GREAT DEAL OF SCIENTIFIC AND TECHNICAL INFORMATION WITH FOREIGN NATIONS. HOWEVER, WE ANTICIPATE AS WE MOVE INTO NEW APPLICATIONS OF BIOTECHNOLOGY THAT WE WILL NEED TO REVIEW THIS ISSUE.

THROUGH SCIENCE AND TECHNICAL AGREEMENTS, THROUGH OTHER FORMAL AND INFORMAL AGREEMENTS, WE MAINTAIN AN EXCELLENT WORKING RELATIONSHIP WITH THE INTERNATIONAL SCIENTIFIC COMMUNITY. WE HAVE HAD SOME MINOR PROBLEMS WITH GERMPLASM EXCHANGES, BUT MOST SUCH ISSUES ARE RESOLVED THROUGH NEGOTIATIONS.

USDA'S OFFICE OF INTERNATIONAL COOPERATION AND DEVELOPMENT (OICD) DIRECTS AGENCY FOR INTERNATIONAL DEVELOPMENT AND COUNTRY-FUNDED INTERNATIONAL TRAINING AND TECHNICAL ASSISTANCE; PARTICIPATES IN THE MANAGEMENT OF USDA INTERNATIONAL SCIENTIFIC EXCHANGE AND RESEARCH PROGRAMS, AND WORKS WITH UNIVERSITIES AND AGRIBUSINESS IN INTERNATIONAL TECHNICAL PROGRAMS.

YOU HAVE SUBMITTED SOME SPECIFIC QUESTIONS REGARDING REGULATION-DRIVEN RESEARCH. USDA IS NOT PRIMARILY A REGULATORY AGENCY. HOWEVER, WITHIN USDA, WE DO HAVE SOME AGENCIES WHICH DEAL WITH REGULATORY MATTERS, SUCH AS THE ANIMAL AND PLANT HEALTH INSPECTION SERVICE (APHIS), THE FOOD SAFETY AND INSPECTION SERVICE (FSIS), AND THE FEDERAL GRAIN INSPECTION SERVICE (FGIS). THE BULK OF RESEARCH ACTIVITIES FOR THESE AGENCIES IS CARRIED OUT BY THE AGRICULTURAL RESEARCH SERVICE. FOR INSTANCE, APHIS FUNDS APPROXIMATELY $6 MILLION IN RESEARCH PROJECTS THROUGH ARS. APHIS ALSO MAINTAINS SOME LABORATORY FACILITIES FOR SPECIFIC APPLICATIONS. THIS SYSTEM SEEMS TO WORK WELL WITHIN USDA. TO PROVIDE SEPARATE RESEARCH FACILITIES FOR EACH OF THESE AGENCIES WOULD NOT BE COST EFFECTIVE.

OF COURSE, DECISIONS BY REGULATORY AGENCIES IMPACT FARMERS AND RANCHERS. DECISIONS BY THE ENVIRONMENTAL PROTECTION AGENCY OFTEN REQUIRE TECHNICAL RESPONSES FROM USDA. AS AN EXAMPLE, USDA PERFORMS BENEFITS ASSESSMENTS ON THOSE AGRICULTURAL CHEMICALS WHICH ARE UNDER SPECIAL REVIEW STATUS BY EPA. THESE REVIEWS ARE DESIGNED TO PROVIDE INFORMATION TO EPA WHICH IT CAN USE IN MAKING A FINAL DETERMINATION AS TO THE FATE OF A SPECIFIC CHEMICAL. IF, FOR INSTANCE, A CHEMICAL IS KNOWN TO HAVE ADVERSE IMPACTS ON THE ENVIRONMENT, IS THERE A SUITABLE ALTERNATIVE? WILL THE WITHDRAWAL OF THE CHEMICAL CAUSE UNDUE ECONOMIC HARDSHIP ON THE AGRICULTURAL COMMUNITY? ARE THERE ALTERNATIVES TO OUTRIGHT WITHDRAWAL, SUCH AS PESTICIDE APPLICATOR TRAINING PROGRAMS, SPECIFIC USE ALLOWANCES AND SUCH? SUCH STUDIES ARE BEST DONE BY USDA BECAUSE WE HAVE THE INFORMATIONAL NETWORK NEEDED TO EXTRACT SUCH DATA.

IN ALL INSTANCES WHERE USDA RESEARCH IS PRODUCED FOR REGULATORY AGENCIES, WE DO ATTEMPT TO ISSUE RESULTS IN A FORM WHICH CAN BE READILY TRANSLATED BY THE REGULATORS. AND, RESEARCH SCIENTISTS OFTEN INTERACT DIRECTLY WITH REPRESENTATIVES OF THE REGULATORY AGENCIES.

THE FINAL SUBJECT WHICH YOU ADDRESSED INVOLVES FEDERAL LABORATORIES.

DR. KINNEY GAVE YOU AN OVERVIEW AS TO THE ORGANIZATION AND ASSIGNMENT OF WORK IN THE ARS LABORATORIES. I AM WELL PLEASED WITH THE RELATIONSHIP WHICH ARS HAS HAD IN WORKING WITH THE UNIVERSITIES, INCLUDING THE SHARING OF LABORATORY FACILITIES AND PERSONNEL. I WANT TO SEE A CONTINUATION AND A STRENGTHENING OF SUCH RELATIONSHIPS IN THE YEARS AHEAD.

THE LAST QUESTION WHICH YOU POSED DEALS WITH THE POLICY TOWARD ESTABLISHMENT OF NEW FEDERAL LABORATORIES AND THE REORIENTATION OF EXISTING FACILITIES. WE MUST MAINTAIN OUR POSITION AS A WORLD LEADER IN SCIENTIFIC REASEARCH, AND THIS MEANS WILL MUST DEVOTE OUR ATTENTION TO PROGRAM IMPROVEMENTS RATHER THAN CONSTRUCTION PROJECTS.

I MIGHT NOTE THAT I HAVE ALSO SUBMITTED FOR YOUR REVIEW A COPY OF THE USDA NEEDS ASSESSMENT REPORT WHICH WAS TRANSMITTED TO CONGRESS LAST YEAR. THIS DOCUMENT COVERS IN DETAIL MANY OF THE SUBJECTS WE HAVE DISCUSSED HERE TODAY. I DO APPRECIATE THE CONTINUING INTEREST OF THE SCIENCE AND TECHNOLOGY COMMITTEE IN THE RESEARCH PROGRAMS OF USDA. THIS CONCLUDES MY FORMAL STATEMENT. I WOULD BE PLEASED TO RESPOND TO YOUR QUESTIONS.

-0-

Mr. FUQUA. Thank you very much, Dr. Bentley.
Now, we will hear from you, Dr. McDonald.

STATEMENT OF DR. FRANK B. McDONALD, CHIEF SCIENTIST, NATIONAL AERONAUTICS AND SPACE ADMINISTRATION, WASHINGTON, DC

Dr. MCDONALD. Good morning, Mr. Chairman.

I welcome the oppportunity to testify before the Committee on Science Policy, Task Force on Science in the Mission Agencies.

We at NASA are the Nation's mission agency for aeronautics and space research. Our goal is to maintain U.S. leadership and pre-eminence in space sciences, space technology and aeronautics.

As I see it today, the state of NASA is healthy, in space sciences in aeronautics, we are seeing right at this moment—we are approaching very rapidly an operational Shuttle, and we have taken off on a very exciting new adventure as we go out and move well along toward planning the Space Station.

The success with which we have achieved our goals in the NASA program can be traced to the very productive and effective cooperative relationships that we have nurtured and maintained over more than two decades and a half with our research partners, the universities, other Federal laboratories, nonprofit research institutions, industrial organizations and a variety of international organizations.

The diversity of NASA's scientific and technical programs require that we maintain different management approaches for science and for the development of applied research and technology in the aeronautics area. These are combined and coordinated by a coherent planning process that insures that we have an overall balanced program, and it also gives us a means of checking.

Here is our long-range program plan that we have just put out for 1986. It especially focuses on the immediate program over the next 3 years. It is a very good barometer for the next 5 years, and it gives some indication of where we think we are going over the next 10 years. This is, for us, a very useful process. It represents inputs from a great variety of sources in the space science area, from the Space Science Board of the National Academy of Sciences, from the Aeronautics and Space Engineering Board of the National Academy of Engineering, from industry, and from our own NASA Advisory Council which is made up principally of people from industry and the universities.

I will first talk about the program management in the Office of Space Science and Applications that manages and plans NASA's space science and application program. It has two principal centers that work directly for it: the Goddard Space Flight Center in Greenbelt, which is primarily our pre-eminent science center within the agency which manages most of the low orbit programs; and JPL, which is concerned with solar system exploration, Deep Space Network.

We also have very major science programs at the Marshall Space Flight Center that manages the Space Telescope. We are just planning the Advanced X-ray Astronomy Facility and other programs, and at the Ames Research Center in Mountain View, CA, where

we have a large life-sciences program, infrared astronomy and other areas.

The scientific breadth of our program is very large, extending from Earth sciences, solar system exploration, astronomy, solar and terrestrial sciences, microgravity sciences, advanced communications, and life sciences. These are closely coordinated with the other Federal agencies, particularly in the Earth sciences program, with NOAA, with the National Science Foundation and other areas, and in astrophysics with the National Science Foundation.

We can break the program down into three major catagories: the flight programs that range all the way from a very large program like the Space Telescope, Galileo, down to individual Space Shuttle payloads—these are supported, and this accounts for roughly 60 percent of the $1.6 billion OSSA budget; Mission Operations, which maintains these missions when they are in orbit, and this is where we sort of get the life blood of new results that flow into the scientific community.

We have seen an ever-increasing length of lifetime. We have the Pioneers. They are now still working after 10 years. The international ultraviolet explorer is going well after 7 years and still having a very crowded observing program.

That is—Missions Operations is a very important part of the science program, and the research base is supplied by R&A, the Research and Analysis and the Suborbital program which you put something on the order of 27 percent of the OSSA budget of $427 million. This research base is the principal support of university research, the proposal to handle standard peer review for quality and relevance. It is also the major funding source for advance mission planning, for the development of new detector technology. It supports NASA's immediate scientific goals and at the same time supports the basic science that is necessary for maintaining national pre-eminence in space science.

The typical university grant from the Research and Analysis Program is on the order of $50,000 to $125,000. These are normally funded for 3 years. They can extend up to $1 million where centers of specialized capability have grown.

The overall scientific objectives of the Space Science Programs are defined in a highly interactive process among OSSA management, the discipline chiefs who manage the various research disciplines, the Space Science Board, the National Advisory Council. This process works. I mean, if you look now as we come up with our 1986 budget, I think No. 1, we tried to establish new starts. It is the clear consensus of the vast variety of disciplines that a mission in oceanography was the first choice of what should be done now. The flight experiments themselves, for a given mission, are chosen by competitive peer review in response to an announcement of opportunity.

The Space Science Program is a national one directed from NASA headquarters. I think we may be one of the few agencies who subject our center research and analysis efforts to peer review by the outside on individual proposals, and where the centers must also compete with the outside world for the opportunities to fly on the missions. It is a very competitive program. I think that degree

of competition is one of the things that has maintained it at such a high level.

The aeronautics and space technology goal is to maintain the United States in a position of world aerospace leadership. It is based on three pre-eminent research laboratories: the Ames Laboratory in Mountain View, Lewis, and Langley. They all have broad capabilities, but they are focused to remove overlap.

The areas of specialization are established by NASA headquarters that provides the strategies, direction and resources. The aeronautics program is very closely coordinated with the needs of DOD and with industry. A significant part of that is the development of space technology for future missions: large space structures, robotics, new forms of propulsion.

Sixty percent of the space technology is conducted in-house. Forty percent goes out to universities and industry. We are shaped very much by the astronomy—by the Aeronautics and Space Engineering Board of the National Academy of Engineering and by our own in-house advisory groups.

The Office of Aeronautics and Space Technology total university runs on the order of $50 million, of which 80 percent is funded through research grants of something on the order of 700 grants per year and roughly $65,000 per grant to 160 different institutions. We also maintain six university Centers of Excellence to develop new technology that we think is going to be important, and then there is a fund for independent research that supports new and innovative technology on the order of $4 million a year at 100 grants per year.

We have also established the Office of Commercial Programs to try to enhance the commercial potential of space, and one of the first steps in doing this is to establish some five centers for commercial development at five universities at the rate of roughly $1½ million per year. This will be continued over a 5-year program. It is in very close partnership with industry, and we hope this will play a very key role in developing the potential of doing commercial activities in space.

Maintaining our scientific and engineering base, a strong supply of scientists and engineers, is extremely important to NASA. We recognize that our succcess depends very, very strongly on the competence of the people that we have working on this program. We try to encourage this.

Graduate students play an active role in many of our programs in space sciences and aeronautics. We have enhanced this with graduate student fellowships. We also try to provide postgraduate training at the NASA centers through a program of the National Academy of Sciences Residents Research Associates that take place at the nine NASA centers.

We try to encourage outreach programs, and we feel that sometimes, such as the recent program to put a teacher in space, is again, an effort to focus on how important we feel that reaching out into the elementary and secondary levels, trying to encourage people in science, mathematics, and engineering at a very early age, is important to our future and is something that we think is very important.

Thank you for this opportunity, Mr. Chairman. I will be glad to respond to any questions.

[The prepared statement of Dr. McDonald follows:]

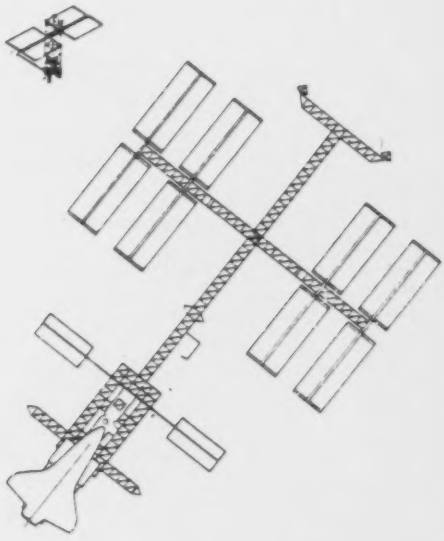
Committee on Science and Technology

House of Representatives

Statement by:

Dr. Frank B. McDonald
Chief Scientist



99th Congress

Hold for Release Until
Presented By Witness
October 4, 1985

Statement of

Dr. Frank B. McDonald
Chief Scientist

National Aeronautics and Space Administration

before the

Task Force on Science Policy
Committee on Science and Technology
House of Representatives

Mr. Chairman:

Thank you, Mr. Chairman, for the opportunity to testify before the Committee's Science Policy Task Force on the important subject of "Science in the Mission Agencies and Federal Laboratories".

I am pleased to participate in today's hearings with officials from other Federal "mission agencies" and from several nongovernmental organizations concerned with the health of this Nation's basic and applied research programs. Much of the success which we have achieved in the NASA program can be traced to the productive and effective cooperative relationships which we have nurtured over two and one-half decades with our research partners in the universities, in other Federal laboratories, in nonprofit research institutions, in industrial organizations and in a variety of international organizations. In my testimony today, I would like to highlight some important characteristics of the working relationships which have evolved over time making it possible for NASA to conduct highly-complex technological missions involving such disparate institutions.

The wide diversity of NASA's scientific and technical programs require different management approaches for science and for the development of applied research and technology. These different management approaches are combined and coordinated by a coherent planning process that ensures the overall NASA program is a balanced and forward looking one.

This planning process begins with an annual review by NASA management of proposed programs for both the prospective year and for later years. These proposals from NASA's program offices at Headquarters have been refined with the assistance of management

at NASA's centers and NASA's advisory committees. The advisory apparatus includes the Boards of the National Academies of Science and Engineering and the Committees of NASA's Advisory Council, as well as leaders in industry, universities and nongovernmental research organizations. This process is of great value not only for setting goals and policy on a continuing basis, but also for providing a measure of progress in fulfilling NASA's overall mission.

The responsibility for program definition, as well as the management, of NASA's basic and applied research is concentrated in NASA's Office of Space Science and Applications and in the Office of Aeronautics and Space Technology. The following discussion focuses on the goals and objectives of their research programs and on a number of factors that are important in defining and implementing these programs, including (1) the value of NASA's relationship with extramural research performers, (2) the role of Federal mission agencies in creating and maintaining a healthy science and engineering infrastructure and (3) the role of NASA field centers in carrying out the Agency's research and technology programs. In addition, a new NASA initiative by the Office of Commercial Programs involving Industry-University-NASA research partnerships is described.

Space Science and Applications

The Office of Space Science and Applications (OSSA) manages NASA's major scientific and applications space flight programs, various research activities carried out with balloons, aircraft, and sounding rockets as well as ground-based research. OSSA has responsibility for about 20 percent of the total NASA program and has institutional management responsibility for the Goddard Space Flight Center (Greenbelt, Maryland) and the Jet Propulsion Laboratory (JPL) (Pasadena, California). JPL is operated for NASA by the California Institute of Technology as a government-owned-contractor-operated laboratory.

Goddard and JPL are the principal NASA centers for the development and operation of unmanned scientific and applications satellites and also play key roles in operating the tracking and data acquisition network for the agency. Goddard has evolved as the major center in NASA for earth-oriented satellites (including remote-sensing) and supports NOAA in the development and procurement of meteorological satellites. JPL has evolved as the major center in NASA for solar system exploration and supports this activity by operating the Deep Space Network used for communications with planetary spacecraft.

In addition to the programs at Goddard and JPL, major space science and applications projects are being carried out at the Marshall Space Flight Center (Huntsville, Alabama) (Hubble Space Telescope development and microgravity research); the Lewis Research Center (Cleveland, Ohio) (advanced communications satellite technology and microgravity science); and at the Johnson Space Center (Houston, Texas), and the Ames Research Center (Moffett Field, CA) (life sciences).

The Space Science and Applications programs span a range of scientific and technical disciplines of extraordinary breadth and diversity: astrophysics, solar system exploration, solar terrestrial science, earth science and applications, life sciences, microgravity science and applications, and advanced communications satellite technology.

OSSA is organized to manage these activities through eight technical divisions which in turn are staffed with appropriate science discipline Chiefs who are expert in these particular scientific disciplines. The OSSA program falls logically into three categories:

- Flight Programs -- includes major free-flying satellites which typically require 3-7 year development schedules and several years of science operations. Total project life from conception through development, science operations, and data reduction and analysis may easily span a decade or more. Scientific satellites have grown significantly in complexity as instrument technologies have advanced. The flight program also includes space shuttle payloads.

- Mission Operations and Data Analysis (MO&DA) -- these programs provide for operational support to science missions beginning about 30 days after launch and for the duration of the planned operational mission -- normally one or two years, except for planetary missions where the flight time may be several years. Funding for data analysis may extend beyond the operational period of a spacecraft because of the time required to process and interpret experimental results.

- Research and Analysis (R&A) -- these programs provide funding for ground-based research and represent the principal source for ongoing support of science investigators at universities and other research institutions. OSSA project funding is administered through contracts and grants which total about $365 million per year. All proposals for Research and Analysis support are peer-reviewed and are re-evaluated periodically for quality and relevance. The R&A program is also a major source of funding for advanced mission planning and for advanced technical development on scientific instruments to be flown on future missions.

The scope of OSSA's programs, including the internal/external balance of these programs was clearly recognized in the report of the Space and Earth Science Advisory Committee on "Research and Analysis in the Space Sciences" (July 1984):

> "In considering the NASA science program, it must be realized that the agency has been given the responsibility for managing and fostering programs of national significance. The importance of the R&A program within NASA can be viewed from two perspectives: as directly supporting NASA's immediate scientific goals, and as supporting the basic science that is necessary for achieving long-term success in the programs in the space and earth sciences for which NASA is responsible.
>
> NASA has a distinctive role as a manager of national programs in that it must integrate contributions from three diverse communities: the universities, the NASA centers, and industry. The efficacy of the total effort depends strongly on maintaining appropriate balances between these components, taking advantage of the special strengths of each, and stimulating each of them to contribute in an optimum way to the total endeavor."

The Research and Analysis, Mission Operations and Data Analysis and a significant part of the suborbital program together comprise OSSA's "research base." This research base provides ongoing support for operational spacecraft as well as the basic infrastructure of support for the conduct of ground-based activities at the NASA centers, in the universities, and in other laboratories of the Principal Investigators and Co-Investigators who make up the core science team for space science and applications missions. A typical university research grant from the Research and Analysis program averages from $50,000 to $125,000 per year. Following a peer-reviewed selection procedure an experiment would normally be funded for three years or more. Some grants are larger, ranging up to $1 million per year in areas where centers of specialized capabilities have grown up in the universities.

Figure 1 provides a breakdown of the FY 1986 budget for OSSA showing the distribution of funds for major program elements. Figure 2 provides a similar breakdown by economic sector. As can be seen in the chart, about 80 percent of the OSSA program is extramural, representing funds spent with universities, aerospace contractors, and other supporting activities.

The scientific objectives of OSSA programs are determined through an interactive and highly iterative planning process which involves OSSA management, the discipline scientists in the OSSA program divisions and field centers, and the independent advisory committees of the National Academy of Sciences (Space Science Board). Also involved in defining program objectives and in assigning priorities are NASA's internal advisory committees organized under the NASA Council. Of these, the most directly involved in the review of ongoing programs and near-term planning are the Space and Earth Science Advisory Committee, the Space Applications Advisory Committee and the Life Sciences Advisory Committee.

It is important to stress the "close coupling" of the flight program and ground-based activities in the research base: The results from successful flight projects flow backwards into the knowledge base for particular disciplines thus contributing to the definition of future science objectives and flight projects. Conversely, ground-based technology efforts supported by the research base provide the basis for enhancing scientific instrumentation thus enabling more powerful tools for future flight projects. The highly iterative nature of this planning process is illustrated graphically in Figure 3.

The distribution of the Space Science and Applications effort among NASA field centers on major hardware projects is heavily influenced by the specialized capabilities which have evolved at the various centers. From time to time specific policy decisions must be made by NASA Headquarters concerning roles and missions of competing centers as, for example, a recent OSSA decision to assign lead responsibilites for on-orbit satellite servicing to the Goddard Space Flight Center.

The relative proportion of in-house/out-of-house development efforts on major hardware projects is a consideration weighed in the "New Start" approval process, which involves a series of presentations and independent technical and cost reviews that culminate in the final decisions as to whether or not to proceed by the NASA Administrator. Project management for flight projects is usually assigned to a center, with systems development and integration assigned to a prime contractor. At times certain flight projects are developed primarily in-house in order to maintain technical skills which are critical to the center's ability to perform effectively the contractor management role which is the typical mode of project management.

The OSSA approach to assignment of flight experiment opportunities and research grants among competing scientists inside and outside of NASA may be unique in that it provides for independent peer review of all proposals including those submitted by in-house NASA scientists. The selection of

proposals received in response to an Announcement of Opportunity are carried out through formal procedures similar to the Request for Proposal and Source Selection Board rules which govern major government procurements. These regulations provide for strict confidence of information received on competing proposals and on evaluations carried out by the Space Science Steering Committee leading to final payload selection by the OSSA Associate Administrator. The objective is to assure selection of the best flight experiments that meet criteria of scientific "merit" and "relevance" to the science objectives defined in the Announcement of Opportunity. Less formal procedures are used in OSSA Headquarters to evaluate smaller research grants and contracts, but all science proposals are subjected to peer review to assure even-handed selection of the highest quality work. The Headquarters Science Discipline Chiefs play a major role in assuring the integrity and effectiveness of the selection process.

Many OSSA projects involve cooperation with foreign scientists ranging from personnel exchanges, to sharing of mission data, to development of major components of complex spacecraft. Arrangements usually entail foreign partners paying for their own instruments and other hardware developments which are contributed to the total effort. Providing launch services as a "quid pro quo" for international sharing of flight opportunities is a well-established consideration in the negotiations. Benefits from international cooperation beyond the obvious foreign policy gains include cost-sharing on expensive missions, and providing reciprocal access to first-class science and facilities between the partners. Trends toward increasingly complex and longer duration missions such as the Hubble Space Telescope -- coupled with growing interest and capabilities abroad -- suggest that international cooperation will be a common ingredient in the definition of future space science missions.

Aeronautics and Space Technology

The basic objective of the NASA Technology Research program is to provide advances for future aeronautical and space systems that will enable the U.S. to maintain a position of world aerospace leadership. The Office of Aeronautics and Space Technology (OAST) organization is founded on three preeminent research laboratories, the Ames, Langley, and Lewis Research Centers. Each center has broad capability for research across the aerospace sciences in addition to providing the major national resource in terms of both facilities and research personnel in their major areas of concentration. The centers, by mutual agreement and Headquarters concurrence, select areas of emphasis to minimize duplication of resources.

NASA Headquarters provides strategic direction and resources for the center research efforts managed by NASA centers. For aeronautics research this direction is responsive to National priorities, Congressional emphasis and technological opportunities as portrayed by the extensive system of industry/government/academic advisory committees. A disciplinary display of the FY 1986 R&T base and systems technology programs is provided in Figure 4. The space technology research program is responsive to needs and opportunities for enabling the capability of planned and forecast missions and programs. Projected system needs are compared against technological trends and forecast advancements to identify areas of opportunity for technological research and to provide the basis for the prioritization of resources. The FY 1986 R&T base and systems technology detail is provided in Figure 5.

As illustrated in Figure 6, approximately 60 percent of aeronautics research is conducted within the agency, primarily at the three research centers. The balance of the program is funded through industry contracts for applied research, and university grants for the more basic research activities. The distribution of these resources is about 70 percent for applied and 30 percent for basic research.

Recommendations of formal advisory groups and ad hoc committees heavily influence the areas of research emphasis and the attendent priorities. Expert advice and guidance is provided by the Aeronautics Advisory and Space Systems Technology Advisory Committees, the Aeronautics and Space Engineering Board of the National Academy of Engineering, and specialized ad hoc groups, primarily under the auspices of the National Academy.

The OAST university program, currently at a $50 million annual level (Figure 6) is funded through research grants, support to research institutes, the establishment of unique Centers of Excellence at appropriate universities, and through various jointly funded programs with the universities and/or other Federal agencies. These university programs characteristically address long-range, high-return and high-risk research topics. The topics and areas of research interest are made known to the university community through the conduct of topical symposia and workshops and are solicited by both formal and informal invitations for proposals.

The major portion (80 percent) of the OAST university program is funded through the research grant process. This activity is intended to extend the Agency's mainstream research in support of the OAST technology program elements. The program is delegated to, and managed by NASA's research centers and provides in the order of 700 grants per year at about $65,000 per grant to some 160 different institutions around the country.

University Centers of Excellence have been established at six universities to develop unique expertise in newly emerging fields such as composite and ceramic materials, computer sciences, and artificial intelligence. These grants average $500,000 per year per school. Jointly funded programs are being pursued with the Federal Aviation Administration to encourage graduate studies in advanced avionics and controls and to accelerate research in such areas as air traffic control and wind shear penetration modeling. Approximately 15 percent of the university program supports generic basic research. The $8 million provides for university needs in graduate and undergraduate curricula development and for the important Fund for Independent Research which is designed to encourage novel and basic investigations more fundamental and/or advanced than the focused OAST research program.

The Fund for Independent Research is managed by the research centers. About one hundred grants totaling $4 million ($40,000 average) are the result of awards to both solicited and unsolicited proposers. This program is under the cognizance of each center's Chief Scientist and a Basic Research Council of leading experts from NASA's centers. Other university programs include specialized education and training in fields such as computational fluid dynamics and aeronautics research.

NASA also participates in Federal University Programs. These include: summer employment for faculty and students; a grant program for Historically Black Colleges and Universities; an employee graduate study program; and an intergovernmental mobility program.

Each aeronautics research center publishes a Research Proposal Submission Guide defining the submittal process. The National Research Council participates in a cooperative process of publishing abstracts of NASA research needs. The centers' Joint Research Institutes serve as networks to the university community. The University Space Research Association provides another networking source of NASA research guidance. Furthermore, there are regular solicitations on both specific and broad research areas of interest that are pursued through Announcements of Opportunity or "Dear Colleague" letters.

Proposal evaluation and selection is primarily an internal process but is frequently augmented by support from university and industry specialists. Research results and products are evaluated by both center and outside peer review groups. A most productive technique has been to assemble all grantees and contractors for a review of research in areas of common interest. All grants and contracts require a final report submittal and they are published through the Scientific and Technical Information Facility (STIF). Many researchers, of course,

publish their results in professional journals and in conference or workshop proceedings. Feedback from the research community occurs both informally through contract and grant monitors and more formally through those experts that participate in the Advisory Groups previously described.

OAST has extensive involvement with foreign research counterparts through both informal and professional exchanges and through more formally established international working groups. The Advisory Group for Aerospace Research and Development (AGARD) provides an extensive basis for mutually beneficial exchanges with the Europeans in aeronautics and to some extent the broader aerospace technologies. An OAST/European Space Technology Center informal working group on technology planning serves a similar purpose for space technology interactions. Through our center's Joint Institutes, internationally recognized experts participate for up to a year as researchers in their programs. The centers also sponsor programs that enable exchange of researchers with France, Germany, Britain, and Japan.

Industry/University/Government Research Partnerships

A year ago NASA established an Office of Commercial Programs at Headquarters to contribute to the maintenance of U.S. technological leadership through increased investment by the U.S. private sector in commercial space activities. This office will encourage private sector investment by aerospace companies and other industrial entities with the potential for manufacturing in space, and facilitate private sector space activities through access to available U.S. Government capability. NASA's specific initiatives in these regards include establishing the Centers for the Commercial Development of Space and increasing the number and type of NASA facilities available for private sector use in space. For both these initiatives, NASA requires documented private sector investment to the activity at the onset of the project.

The Centers for the Commercial Development of Space are new. They have been established to stimulate high technology research, development and production in the space environment. This research should eventually lead to the development of new products which either have commercial potential or contribute to possible commercial ventures. Twenty-one proposals were submitted in June 1985. These were reviewed by a group of 25 peers including 17 from the private sector. Of the 21 proposals, five were selected for funding in FY 1985: Battelle Laboratories, Columbus, Ohio; Vanderbilt University, Nashville, Tennessee; University of Alabama,

Huntsville; University of Alabama, Birmingham; and the Institute for Technology Development, Jackson, Mississippi. The Centers are unique combinations of industrial, university, and government partners and some contain up to ten industrial corporations, five universities, and substantial support from State and local governments. NASA will fund these Centers for a period not to exceed five years after which they are expected to become self-sustaining. First-year NASA support ranges from $750,000 to $1,140,000 for the Centers, and the non-NASA support is significant. Six additional Centers are planned for FY 1986. Proposals from which to make those selections are due on April 15, 1986.

The Office of Commercial Programs will also fund the development and/or fabrication of multiuser facilities to help facilitate commercial use of space. These facilities are proposed by NASA's field centers and, in addition to conceptual analysis and a project operating plan, require documented company interest in using the facilities with an indication of the amount of resources a company will commit to support their portion of the R&D activities. Facilities that have either been proposed and/or are funded include the variable temperature environmental chambers to conduct protein crystal growth experiments, multiple experiment processing furnace and the advanced automatic directional solidification furnace to conduct melt growth experiments, and the microgravity materials science laboratory at the Lewis Research Center. Approximately 50 percent of the FY 1985 budget for commercial programs supports Centers for the Commercial Development of Space, a unique university/industry/government partnership.

Maintaining the Base of Highly Qualified Engineers and Scientists

The health of the Nation's aeronautics and space research programs is directly dependent on maintaining an adequate supply of qualified scientific and technical personnel and adequately equipped facilities. NASA considers a strong, interdependent relationshp between NASA and the educational community essential to fulfilling the needs for scientific and research manpower. To this end, NASA has developed and/or utilized many programs to integrate students and faculty into the research programs of the agency.

A new and innovative program to stimulate interest in long-term research opportunities was initiated by NASA in FY 1984 with the support of the University Space Research Association. NASA assists in the formulation of credit courses at the undergraduate level for the design and exploration of advanced systems concepts for future space missions. When combined with summer internships at NASA, these courses provide insight and training for 50 young engineers and scientists.

The NASA Graduate Student Researchers Program, initiated in 1980, provides approximately 80 new fellowships each year to U.S. students pursuing either a masters or doctorate degree in disciplines related to the agency's mission. NASA also awards approximately 250 fellowships in conjunction with the American Society for Engineering Education to U.S. citizen university faculty to conduct research during the summer at the NASA centers.

The NASA Resident Research Associateship Program, administered through the National Research Council, provides opportunities for approximately 200 postdoctoral scientists and engineers to perform work of their own choice which is compatible with the research interest of NASA. For recent doctoral graduates the program provides an opportunity for concentrated research in association with selected members of the NASA laboratory staff, often as a climax to formal career preparation.

NASA's university programs provide an institutional approach to the development of strong, mutually productive relationships between NASA and the university community. Such programs aid in the development of scientific and technical personnel who become the ultimate research performers for NASA, whether they be civil service, university faculty or industry.

Mr. Chairman, that concludes my testimony. Thank you for inviting NASA testimony today.

Mr. FUQUA. Dr. McDonald, I know on the last page of your prepared testimony, you said in the prepared statement that approximately 80 new fellowships each year go to U.S. students pursuing masters or doctors degrees. How many all total do you have? Is that new students or is that——

Dr. MCDONALD. That has only been in our fellowship program which was very, very strong in the 1960's. We have only had that in operation 1 year, so we have on the order of something like 50 students, and we hope to grow that to 80. Our goal is to build that up to a modest program on the order of 200 students a year.

Mr. FUQUA. Very good. Dr. Bentley, yesterday we got in with Dr. Kinney and Dr. Jordan about advisory committees and so forth, and I know the two agencies that are sitting on either side of you, DOE and NASA—DOE has the ERAB committees that advise them which are outside people.

NASA has the Space Science Board and other advisory——

Dr. MCDONALD. And the ASEB——

Mr. FUQUA. Outside groups. I was noting in the green book, on the back page you had the advisory committee. If my calculations are correct, there are 31 people. They are not counting the Executive Secretary of which 12 of these, almost half, come from within the hierarchy of the Department of Agriculture here in town, and all of the rest are associated with Agricultural Experiment Stations and so forth, or research facilities, and very few come from industry or from outside or scientists that may not be in the administrative end of that.

Do you think you get the right input from these advisory groups? Of course, in the case—I will let them defend or condemn their boards, and I am not being critical. I am only asking a question, because that is what we are trying to find out here. It seems like this limits the amount of outside interaction that can come into play, particularly in some of the broad policy issues that the Department might be interested in or should be intersted in.

Dr. BENTLEY. Mr. Chairman, I would like to elaborate a bit on this advisory group. This is sort of the top group that was established by Congress to be the coordinating and oversight as far as planning.

You are recognizing the way it operates. That is that there are within a whole series of groups that represented commodities, groups who might, say, have research committees, cattle, citrus industry, and poultry, and so forth, have a whole labyrinth of committees that advise on this, and these kinds of recommendations are made by the user, producers and scientists that are associated with those particular areas. And their recommendations flow into the research committee and ultimately get incorporated into the recommendation or are given consideration in the recommendations as they emerge from the overall joint council.

In addition to that, within the experimental stage——

Mr. FUQUA. It is kind of a filtering system.

Dr. BENTLEY. Yes. Every State has some type of an advisory committee, and sometimes they are rather extensive within States that deal with plant pathology or with products, agriculture, so forth,

and then the Agricultural Experiment Stations themselves have a series, have some advisory groups where they call on scientists.

In the Competitive Grants Program we have a very active and excellent science advisory committee, and then within the Agricultural Research Service, they, too, have a series of committees that give them advise on water technology and so on.

So, we think we are getting that. On the other hand, I think it is an area of such scope and such importance that we are looking for better ways to achieve this.

In fact, I am very pleased that I have as my deputy Mr. Dan MacPherson who is here this morning, and who has had a career with a major food company, General Mills, and has retired from that position and has been willing to assume decisional responsibilities and serve in this, and that is part of the reason I am delighted is he will provide a decisional link for us with the industrial sector.

Mr. FUQUA. Dr. Trivelpiece, how do you find advisory committees who are trying to bring forth areas of science policy that they think, particularly within that field, to the attention of the people in DOE and your particular case?

Dr. TRIVELPIECE. I think they are indispensable. It depends on the precise circumstance which is involved. In some cases, in fields such as high energy physics, the High Energy Physics Advisory Panel plays a very key role. That is more or less a closed group, and we need the advice from them on what they regard as the priorities within their own program area; what would we be doing in order to try to make advances in that field. And then it ranks from that to what I call a down and technically intensive type of advisory functions. There are several of those, the Nuclear Science Advisory Committee and so on.

It ranges from those to the one you mentioned, the Energy Research Advisory Board which is the highest level advisory comittee in the Department and reports directly to the Secretary. It consists of about 26 members who are chosen broadly for their national leadership characteristics and so on, and they look across the Department as a whole and try to provide what I would call up-and-out advice—that is, where should the Department be going globally in its overall mission activities in science and energy and national security? They tend to look at things from time to time of a specific technical nature.

For example, the Fusion Advisory Committee is technically intensive and advises the program on specific technical directions; as reviewed by a separate committee within ERAB on the fusion program—the one in ERAB was to look at the program as a whole and where it is going in the national context.

So, it is an indispensable function within the Department to use these advisory committees, and there is not a fixed simple formula by which they are used. But it depends on the circumstance, and I think they are very well tailored to our needs. That includes things like the Petroleum Council, and the Coal Council as well, which tend to be larger bodies that look at the industry as a whole.

Mr. FUQUA. Dr. McDonald.

Dr. MCDONALD. I think they can be a pain. They can be a headache and they sometimes tell us things we don't want to hear, but I

think they are absolutely invaluable, particularly in the space science area.

If we look at the Space Science Board—and what isn't generally recognized is that the real work of the Space Science Board is done by a very extensive network. I think there is some eight program committees.

Gene Levy, who will testify later this morning from the University of Arizona, was head of the complex, the Committee on Planetary Exploration, and it is these committees who really get in and sort of chart out our future in the space science area.

I think they have done a truly outstanding job in trying to give us advice and guidance, and part of the problem is they have filled our plates with things that will keep us busy for the next 10 years, and we have trouble doing it all, but we do need them.

Mr. FUQUA. One of the questions that came up yesterday, and I think Dr. Kinney mentioned it, was that one of the advantages of having a GOCO lab was the fact that the freedom that the operator of the lab, whether it be the university consortium or others, would have an opportunity to try to retain and keep some of the stars and superstars.

I know DOE—I think exclusively all of our labs are operated as GOCO's, with few exceptions.

Department of Agriculture is probably GOGO's, and NASA with the exception of JPL is the only one that comes to mind right now.

Dr. MCDONALD. That is the only one, yes.

Mr. FUQUA. Maybe this is addressed to all three, but particularly to you, Dr. McDonald and Dr. Bentley. Not necessarily that they have to be a whole structure changed to become GOCO's, but how can we operate the GOGO labs—that is Government-owned, Government-operated, for anybody that is not familiar with all this lingo that goes on around here—so that we could retain some of the top people. I know the Naval Research Lab is operated in that same fashion. It appears to me that there is a great opportunity or possible great opportunity in, particularly NASA, and USDA, for some improvement, and maybe through congressional- acts in trying to free up some people or free the regulations and maybe the bureaucratic impediments in trying to retain the top flight people that you need in some of those areas.

Maybe you would like to comment.

Dr. MCDONALD. Yes, I think we are particularly proud of the vigor and the excellence of the eight GOGO labs that we have. That doesn't mean they can't be improved. We are studying in line with the Packard report——

Mr. FUQUA. This is what I am referring to.

Dr. MCDONALD. Right. The various ways one might change the system, and I think it can range all the way from converting to GOCO's to much simpler changes that would simply change the compensation packages and would make it possible to put together packages to keep both vigorous management and keep—attract and keep the sort of all-stars in both engineering and science.

So, I think in the long run that is going to become a serious problem, and it will need to be addressed.

Dr. BENTLEY. Dr. Kinney pointed out we have a limited number of these arrangements, and so far they have been identified with

management of a facility that is located on the university campus is a good example of that, and where it would be—there is an existing establishment that can take over that responsibility, and there is a shared concern about the goals and functions of those labs.

I think that the problem as I understand it so far in the administration—I don't know the details, but one of them is that the matter of accountability—how do you delegate and agree on an operating plan? But then there is a kind of an accountability that comes to the agency that almost says that they have to have absolute oversight almost day by day sometimes, and that makes it a little difficult. Sometimes, if we work on those we will have to find a mechanism that can delegate greater responsibility to the person operating the facility.

That is one of the questions, and then some of the other employment practices that have to be transmitted to the university, say, makes it difficult for the university to comply with its own set of regulations and those that affect Federal funding programs.

Mr. FUQUA. I am thinking not necessarily a university operating—we have Dr. Trivelpiece in the Department of Energy—the University of California is operating several of the labs, but there are several that are operated by a consortium of universities, which are separate from the management of the university.

Dr. BENTLEY. Yes, sir.

Mr. FUQUA. And that was what I was referring to, if that were feasible?

Dr. BENTLEY. I think though that kind of arrangement would be feasible. I don't recall right now of a one except part of our laboratory that we are talking about on genetic suppression laboratory that we call it for a short name, at the University of California at Berkeley as part of our western regional laboratory. There we have a joint venture that we do involve other universities in programmatic development, not necessarily management in the program, and we think that has a great deal of appeal to us. We could go to a consortium of universities or organization to operate a laboratory.

I guess in agriculture it is somewhat different in terms of our tradition, say, than it is in energy. Energy laboratories, it is my recollection some of them are in the newer areas, so whereas the laboratory in agriculture in Peoria, the people in the lab in Peoria, utilization of the laboratory has its origin with a specific groups and organizations that see that laboratory with some proprietary sense that they are associated with it and maybe make if a little more difficult for——

Mr. FUQUA. In other words, the proposed change may not play well in Peoria?

Dr. BENTLEY. Right. You have helped me make or illustrate a point.

Now, so we would have to look at those in a little different way. We have industry relationships with most of these, look to it if it is a Federal laboratory, they feel that the Federal Government or the Federal Government through the ARS should operate that laboratory. But I certainly am not opposed to looking at the opportunities for this because of that—the statement that you made earlier that we have to think about new relationships to accommodate changes

taking place in science and nature of activities and I guess the whole area of molecular biology and biotechnology is pressing it, compressing the time frame that we can do these. Where we have gone at more leisurely pace prior to these kind of development it is coming in more rapidly, and I think very it is very exciting because I think it opens new opportunities for us.

Mr. FUQUA. Did you want to comment?

Dr. TRIVELPIECE. One of the concerns is that what are those functions in science and technology for which being a government employee is an essential characteristic and to look at that and then decide perhaps that other things, other areas could be done under contract and subcontract modes. There are things which the Department has which we do regard being essentially in environmental measurement laboratory. Upper New York is populated by Federal laboratories.

So there are functions that are essential and perhaps should be looked at in that light. It isn't necessary that everybody be a Federal employee in the science arena. That would permit a salary arrangement different from that which is presently involved.

Mr. FUQUA. Most of the agencies have separate offices within your agency breakdown that support extramural research. If I were an individual researcher and wanted to apply, is there a central office somewhere that I could go and find out or get on the mailing list or find out where I might apply for a research grant, or do you have to go to all the different people that handle that extramural research?

Dr. BENTLEY. I would respond yes, there is a central office and its notification process for the competitive grants, which are really investigator driven type of requests, although they do involve an institutional dimension as well. There is a central office for making application time scale.

With regard to the State Agricultural Experiment Stations, the actual grants, the grants are made on a block grant basis to the States and that then is the subject of the allocation to projects would be done at a State by State level, by the State Agricultural Experiment Station director. Then in the Agricultural Research Service, where there are grants or agreements and so forth, those are initiated more through institutional arrangements. For example, in the area of water—in the water research there is an effort to create a program at a university that might be worked more through the university director to have an Experiment Station. So, yes, there are specific locations and it is identified. We attempt to reduce the confusion as to that issue as much as possible.

Dr. MCDONALD. I think we use it as a performance test to try to find the right place in NASA as to where one should go. We don't make it particularly easy, particularly as we do have two different lines. The aeronautics and space science area, I think the process actually—there is also an office of university programs which, if you go to that, they will sort of almost immediately direct you to the right door. If one makes contact with our Office of Space Sciences and Applications, or with the Office of Aeronautic and Space Technology, I think you can immediately sort of get directed to the right office where you can get the required information. So we don't, as I said in the opening statement, we don't, we really have

several lines of business that we are in, and our relations with the extramural partners are handled in a different way by those organizations. We think in each case it is more efficient and so I think the system is a good one, but I myself constantly get calls by people who want a new experiment or new technology and we direct those to them. So I think the system works and works well in our particular case, without having a central function.

Dr. TRIVELPIECE. There isn't a simple central, organized office within the Department that handles this, because of the broad diversity of things in which the Department is involved. There is a networking system of information that causes most people to know more or less with reasonable accuracy where to begin applying and are directed to the right individual in terms of proposals. But things appear in the Federal Register in some circumstances and other circumstances Commerce Business Daily—a program opportunity for where it will be competitive bid. Unsolicited proposals sometimes end up in the wrong in-box and by an informal communication with the network in the Department, they eventually end up in the right one. Not necessarily do they all get funded. They end up being reviewed in the right place.

Mr. FUQUA. Dr. Bentley, since your department—I am not referring to you—the Department of Agriculture is probably the great grand daddy of all of——

Dr. BENTLEY. Almost true.

Mr. FUQUA. Of all the activities here, I am trying to think of 20 to 40 years down the road, and management and the way things are done. If you, without thinking about it, OMB and all the other things, but if you could rewrite the acts of the Morrill Act and Hatch Act and Evans-Allen, and McIntire-Stennis and all the others, to take effect at the year now, or year 2000 or past the year 2000, what long-range needs do you see in agriculture research and ways to achieve those in the modern society that we live in?

Dr. BENTLEY. Mr. Chairman, that is a big question. Let me give you my view, some impressions that I would have.

First, I would say that turning to the fundamental philosophy, I see a great deal of merit in the Federal-State system that we have had over the past century and so I would preserve that concept.

Now, getting out to how you would implement it, I believe that to do this there needs to be some funding on the Federal side, in terms of grants.

I would look though to some consolidation under two, perhaps three major headings. One, I would think in the formula grants or block grants I would attempt to reduce the number of units or boxes so to speak, that funds came in. You listed various activities. They are all related, they are all carried out in institutions. I would try to think in terms of one major set of block grants. That would give a great deal of autonomy to the university or the cooperator in using these funds and that there could be through agreement and prior discussion, priorities reflecting the activities that come together in a book such as this, or we might want to expand it or change it. I would have that. The other major part, I would maintain a formula block grant concept for assuring a capacity of our country to do this kind of activity.

The second part that I think there is a need for a competitive peer review and more investor-initiated kind of activities. We have a Competitive Grants Program now. You have been familiar with the experiences we have had over the years to get to where we are today in the acceptance of this by research communities. I see some. I would talk about considerable expansion there to focus in on high priority research areas and the application of science to our food, fiber, and nutrition system.

The third part of the activity—and perhaps I should say there are four parts to it—the third part I think that the Department of Agriculture has not been as active in providing funding on some types of, on a matching basis or for high priority needs areas for facilities and state-of-the-art equipment that is needed to accommodate the changes that are taking place in science and technology and their application to universities.

There has been a—much has been done, but I think we are moving as you give time horizons of 10 or 15 or 20 years, I think we are going to need that. For that reason I mentioned the facilities bill as a section within the 1985 farm bill as an example.

Then I believe that the Department of Agriculture should have a clearer mandate in support of scientists. That is, the development of scientists in particular. As I see it, the Federal enterprise and do the business in at the graduate level or postdoctoral level of developing the kind of expertise and facilitating the development of expertise.

And I would think that we should have a longer term commitment here that would make it possible for the Department to do things that would be more parallel to the comments made by my colleagues this morning, in other parts of the Federal Government where they have been able to do more in the development of scientists and so on.

Those are four areas that come to mind. I would want to be sure though that as we talk about expanding the program, I am thinking about looking at our natural resources and getting detailed information. I am talking about water and soil preservation and nutrition and diet health areas. I am making a very broad statement. I am not trying to delineate it to the scope of things, because of the importance of our food and fiber system to our people and to our economy.

Mr. FUQUA. And particularly on petroleum-based products?

Dr. BENTLEY. Yes, sir.

Mr. FUQUA. Pesticides and fertilizer and all of those?

Dr. BENTLEY. Yes, sir. I suspect that, if I may add an additional one, the matter of science as it relates to agriculture is the same as it is for all of our other sciences. That is, we have to think in terms of the international dimensions and we are in a global society in terms of science and in terms of agriculture, and weather I think that is well known by many segments of agriculture. But still many people feel that our system is highly domestically oriented and that there is science in other parts of the world, scientific developments are taking place everywhere and U.S. agriculture has to be a part of this.

Mr. FUQUA. Mr. Volkmer.

Mr. VOLKMER. I would like to ask Dr. Bentley. My understanding of the answer to the chairman's question regarding the changes to be made would be basically that you wouldn't change the research base that you are presently using in the system, Federal-State relationship that you are presently using—that you may use to rearrange the method that system operates as far as funding.

Dr. BENTLEY. Yes, sir.

Mr. VOLKMER. That is correct?

Dr. BENTLEY. Yes, sir, Mr. Volkmer, I would feel this way because I am so convinced of the concept and philosophy we have. But we could streamline the system of how we fund it, and then not have to spend as much time as we do on some of the parts of it. Because when, in the final analysis it is done by people and institutions that are committed to doing this work, I think we could probably spend less time on those activities and talk more about priorities and directions for research, responses to problems and so forth.

Mr. VOLKMER. I have no further questions.

Mr. FUQUA. Thank you, gentlemen, very much for joining us this morning. We appreciate your contributions.

Dr. BENTLEY. Thank you. We appreciate being here.

PANEL 2: MISSION-AGENCY SUPPORTED EXTRAMURAL RESEARCHERS

Mr. FUQUA. Our second panel will consist of those policies and relationships from the point of view of the mission agency performer. They include Dr. William F. Miller, president and chief executive officer of SRI International; Dr. Eugene H. Levy, Lunar Planetary Laboratory, department of planetary science, University of Arizona in Tucson; and Dr. Marvin E. Ebel, associate dean, graduate school, University of Wisconsin in Madison; and George H. Dummer, director, office of sponsored research, Massachusetts Institute of Technology.

Dr. Miller, we will begin with you.

[A biographical sketch of Dr. Miller follows:]

DR. WILLIAM F. MILLER

William F. Miller, Ph.D. is the President and Chief Executive Officer of SRI International. SRI is an independent, non-profit institution whose activities range from management consulting to scientific research. As president of SRI and an internationally known speaker, Dr. Miller has focused attention on the need for stimulating innovation and revitalizing industry by building on the nation's technological and entrepreneurial strengths.

Dr. Miller was educated as a physicist at Purdue University where he received his Ph.D. in 1956. His career history includes experience in high-energy physics, computer science, university administration and as a business consultant and venture capitalist. He joined Stanford University in 1965 as head of the Computation Group at the Stanford Linear Accelerator Center. In 1970 he was appointed Vice President for Research and in 1971 became Vice President and Provost. He became the first Herbert Hoover Professor of Public and Private Management in Stanford's Graduate School of Business in 1979. He is currently professor of Public and Private Management and of Computer Science at Stanford.

Writer, lecturer, educator, executive, venture capitalist, businessman, investor, managment consultant, nature and travel photographer, Dr. Miller is a Fellow of the Institute of Electrical and Electronics Engineers and the American Academy of Arts and Sciences. He was recently appointed as a member of the National Science Board of the National Science Foundation.

Dr. Miller currently serves as a Director of Varian Associates, Pacific Gas and Electric Company, Fireman's Fund Insurance Company, First Interstate Bancorp, and First Interstate Bank of California. He was founding partner of the Mayfield Fund.

STATEMENT OF DR. WILLIAM F. MILLER, PRESIDENT AND CHIEF EXECUTIVE OFFICER, SRI INTERNATIONAL, MEMO PARK, CA

Dr. MILLER. Mr. Chairman, before I begin my testimony, I want to say as many of our predecessors on the earlier panel did, that we certainly applaud the effort of this committee in examining science and technology. There are a lot of immediate and pressing issues that our Nation faces not only in the leadership of Government, but in the long-range education.

Now, turning to my own testimony, SRI International is a not-for-profit research and consulting organization. We have about 2,800 people worldwide, 500 Ph.D.'s, and 1,200 Masters degrees, which means really about two-thirds of our staff are professional and professional performers—about one-third is the support staff. We work purely on a contract basis and we are entirely self-supporting, and by that I mean that we have no endowment, we have no subsidies. We have to really scramble around for our work, we are very competitive in that regard, and that would distinguish us from other producers, if you like.

We are different from industry, we are different from a national laboratory, we are different from the university in that regard, and in many ways, we see ourselves as sitting between universities and industry and bridging that gap in between.

Of the revenue of SRI International, in 1984, we did about $194 million of research, and this year we will go over about $210 million. About 55 percent of the revenue comes from Government agencies. The majority of that is from the mission agencies, such as Defense, HSS and NASA. We also do work for other agencies, the National Institutes of Health, National Science Foundation, and we do work for States, regional governments, city governments and for foreign governments.

Our commercial clients include most of the Fortune 500 companies, as well as major financial institutions and industrial organizations throughout the world. We do have a world view, very global view, and it is that global view that helps us with American companies to compete globally.

Our main laboratories are located in Menlo Park, CA, though we also have offices worldwide—in 12 other countries, other than in the United States.

Now, we are larger than most of the not-for-profit research institutes, but we are very similar in character. We provide a unique and useful bridge between research and commercial phases of new technologies. We do that in many areas. So some of the smaller not-for-profits are much more focused on single subject areas, whereas we have a very broad multi-disciplinary focus at our institute. There are a number of others similar to us. I have submitted for the record the annual reports of others like ours, but I am going to talk principally about SRI and what we do, because that is what I know best, and I can speak about what we do better than what they do.

Overall, the not-for-profit research institutes as identified by the National Science Foundation, receive about $785 million annually for Federal research and development. Roughly, a third of this is in the basic research area, which means that we perform about 8 percent of the basic research for the Nation.

The institutes vary from the specific focus that you mentioned to the broad and multi-disciplinary ones, such as SRI. SRI covers the full spectrum. About 20 percent of our research is basic research by any kind of measure. Most of the support comes from either our own internal support or from NIH and from the National Science Foundation—the more basic research agencies.

So about 20 percent is basic research, about 10 percent is really pure commercialization—where we really develop a commercial product which some companies put into manufacturing and practice. We don't do manufacturing but we do the product design, and the development of it, and then someone else manufactures it. And there are several good examples of that. For example, the Savin copiers that are sold in the United States have been designed by SRI, manufactured, by Rico in Japan, marketed by Savin in this country.

We do that in drugs. We develop drugs for drug companies. We will sometimes do the testing. We do not do the manufacturing but it goes all the way to the commercial side.

This is one example of how institutes that are not-for-profit are really at their very best, is when they can take an idea from the basic research phase, all the way through to some commercial phase. You will see it all across the whole spectrum of developments. This is 20 percent basic, 10 percent commercialization. About 70 percent, the remaining 70 percent, then, is bridging the gap between basic research and commercialization.

Another way in which we feel that we are working the very best, is when we can take this broad collection of talent and capability and bring it to focus on a single company, or for that matter, sometimes on a regional, a city or Government problem. We have a process which we call innovation research where we will bring together teams of scientists, business people, engineers from across our institute to bring them to focus on the strategy and the development for a given company, a U.S. company, or for some types for a State.

We did a major study in Mid-America Trust which covered all the activities of Mid-America and how to revitalize that. We brought together talent from across the spectrum of the whole institute in doing that.

Other organizations to some degree do this. I think our breadth makes us unique. I suspect if you say you are unique you would be hard pressed to find organizations that have that kind of breadth. We have another advantage, and I suppose it was best illustrated by Henry Hansmann of Yale, who pointed out that the advantage of a not-for-profit producer is that we have both the discipline of the market, on the one hand, but that is supplemented by an additional protection given the consumer by this broader contract, that is, the organization's legal commitment to devote its entire earnings to the production of services. We have to invest our profit in the charter purposes of our organization.

We do have to make a profit. We have to make a lot of nonprofit so to speak to support our facilities and buy our own equipment and support our own internal research. But it has to be reinvested in the charter purposes of our organization. So we have that competitive aspect of the marketplace, but at the same time, the consumer has that protection knowing that we are going to reinvest what we do in their interest. We can look at things, therefore, in a somewhat broader view than publicly-held, for-profit organizations and yet a more businesslike view than that which you have in a university environment.

Now, the not-for-profits have been successful in providing solutions to a number of things that have changed the country. At SRI, for example, we developed the technology and the systems for the magnetically encoded bank checks. But not only were we able to develop that technology, but we had a business consulting group who could show the banks how to introduce that, how to develop the systems, how to utilize it after this technology had been developed.

I suppose another well-known example is the example of Battelle, where their scientists developed the copying system later known as xerography that led to the invention or patent based on which Xerox developed the copier.

Southwest Research Institute has been doing a lot in improving automobile engine efficiency and also in the efficiencies of fuels and lubricants. They have been very heavy in that part of the industrial research activity.

There are other examples that show who we can bring that variety of disciplines to bear on a single problem.

In terms of the way in which we acquire support for research, we participate in a very broad way. We participate through competitive contracts as almost any industrial contractor would. We apply for grants which are, one, in response to a general program announcement. We support technical and engineering support contracts, which are a subset if you like, of the competitive contract process.

We have a number of cooperative agreements which require cost sharing with Federally funded research and development centers and of course, we submit unsolicited proposals.

The not-for-profit institutes I mentioned cover this entire spectrum, but we account for a very small part of the total of research spending of the Federal Government. While we are more industry and business oriented than universities, we are more academic on the other hand, than research laboratories.

As the economic pressures increase, corporations, the industry and universities on the other hand are reaching into new areas of funding. The Industrial Research Institute, for instance, which represents interests of industry here in Washington, is conducting a study on how the results of federally-funded support can best be channeled into the private sector. The competition for research funding has grown, and with it there has grown demand for more efficiency.

This places an increased emphasis on the management of research, which is the quality that is at the center of the not-for-profits. Because we do have to manage ourselves well, to have a sur-

plus to reinvest in ourselves, we have to manage our research activity, we become good managers of research.

There is another change that is taking place in research. This is brought about by the change in procurements such as the Competition in Contracting Act, which has had an adverse impact in research in some ways. While indeed the drafters of the act did not intend that research should be procured on the same basis, for example, as equipment should be procured, this increased thrust for competition has produced certain notable effects, that there is a tendency to look at price rather than to look at the scientific expertise. This is most likely to have its effect on unsolicited proposals. If a program manager who is looking at an unsolicited proposal is having to think how could I show this has been competitive, it is very difficult to do. The program officer will look at unsolicited proposals and say this may be the best idea that has come around in a long time, how do I decide whether the best idea has been competitive or not? So I think it will have some tendency—certainly won't eliminate the trend or the acceptance of unsolicited proposals—but it will have some tendency to cause the program officers to be looking at the price as opposed to the scientific expertise or the quality of the idea.

In general, I would say that the basic system on which we work with the mission agencies is a good one. Their proposal solicitation is orderly, their review process for grants works very well. I believe that this area of the unsolicited proposals may not be getting enough attention. We need to get these new ideas, better ideas especially, into the mission agencies.

In a recent Rand report—Walter Baer made a report judging the quality of interdisciplinary policy research by independent research centers, he judged this on the basis off five criteria: (1) policy orientation—institutional commitment; (2) access to information; (3) independence; (4) scale and continuity of effort, and skilled personnel; and (5) incentives of performance.

On that basis, Mr. Baer found that the independent research centers rated the highest on that scale. These criteria are still valid. We believe industry and universities both moved toward the center of technology spectrum because of financial pressures, and that both will be making themselves more visible in the process.

Not-for-profit research institutes, being a smaller part of the total, have often not had visibility. We are often left out of either legislation or when agencies are thinking about the people who they should turn to, to be suppliers of their research.

That sums up my testimony, Mr. Chairman. I think not-for-profits provide a very special role in American science and technology, perhaps the best way to say it is that we organize our people as well as knowledge in a somewhat unique way.

[The prepared statement of Dr. Miller follows:]

Testimony

on

Science in the Mission Agencies --

Extramural Researchers

before the

Science Policy Task Force

Committee on Science and Technology

of the

United States House of Representatives

by

William F. Miller, Ph.D.

President and Chief Executive Officer

SRI International

October 4, 1985

Mr. Chairman, my name is William F. Miller. I am President and Chief Executive Officer of SRI International.

Before beginning my testimony, I should like to take a moment to laud the initiative of this Committee in attacking this all important issue of Science and Technology Policy. There are many immediate and pressing issues that our nation must face through the leadership of our government. But for the long term, there is no issue of greater importance to our health, welfare, and security than our policies for science and technology and the companion issue of education. The effectiveness of these policies to a large measure will determine whether we, as a nation, can compete. With wit and wisdom, we will not only compete economically, we will define the frontiers.

Now, to the testimony. SRI International is a sole-supported, not-for-profit research and consulting organization with approximately 2800 employees, of whom about 500 hold Ph.D's and 1200 hold Masters degrees. We work on a contract basis and are entirely self-supporting. Our revenues were $193.4 million in 1984 and will be over $210 million this year. About 55% of our revenue comes from government agencies, and the majority of that is from mission agencies such as the Department of Defense, HHS, and NASA. We also do work for state, local and foreign governments.

Our commercial clients include many of the Fortune 500 companies, plus major financial and industrial organizations throughout the world. Our international view helps American companies compete globally.

Our laboratories are located in Menlo Park, California. We also have offices here in Washington, D C., in New York and Chicago, as well as in 12 major cities abroad.

While larger than most of the not-for-profit research institutes, we are similar in that we provide a unique and useful bridge between the research and commercial phases of new technologies in many areas. Much of our work is done for clients in business and industry. We help move research out of the laboratory, into development and into the market-place. Thus, SRI, Battelle Memorial, IIT Research Institute, Gulf South Research Institute, Midwest Research Institute, the Research Triangle Institute, Southwest Research Institute, and the Southern Research Institute serve as technology transfer agents, synthesizing scientific developments into new applications. But we do more than that, we also assist industry in the setting of technology strategy, forecasting markets, etc. We are unique and important organizations that bridge the gap from basic research to commercial development.

Overall, non-profit research institutes, as defined by the National Science Foundation, receive about $785 million annually from the Federal government for research and development. The roughly one-third of non-profit institution R&D devoted to basic research is almost 8% of the national total.

The institutes performing this work are varied and their focus ranges from almost single concentration to those whose performance is multidisciplinary. I will submit material from the other institutes as part of my written statement. But let me describe more specifically what SRI does as a way of describing the group of multidisciplinary institutes. Approximately 20% of SRI's work is basic research, performed for government and industry. Another 10% is commercialization where we help clients in the final stages of product development. The other 70% is applications research, falling across the full spectrum, from science to the marketplace. Approximately 65% of our overall work is laboratory based.

There are two areas where we are at our best. The first is that ability I have just described; taking an idea from research to commercialization. The other is our ability to build multidisciplinary teams to solve a company's problems. We have, for instance, a standard technique called 'Innovation Search' which brings our scientists, engineers, analysts, economists and management experts together to identify new business opportunities for a client.

Other organizations do this to some degree, from universities to major corporations. However, to quote Henry B. Hansmann in the Yale Law School Review, "The advantage of a non-profit producer is that the discipline of the market is supplemented by the additional protection given the consumer by another broader 'contract', the organization's legal commitment to devote its entire earnings to the production of services." We must reinvest our excess of revenue over expenses in the Charter purposes of the Institute.

Thus, we can look at things with a broader view than would a publicly-held "for profit" company with its short-term, quarterly earnings focus, yet with more business-like view than that of the university environment. We can set up two screens for an idea, one to prove the technology and the second to prove its marketability.

Not-for-profit institutes have been very successful in providing solutions which have positively changed American society. At SRI, for instance, we not only developed the technology and the system of magnetically encoding bank checks, but also were able to help the banking industry implement the changes necessary to make that technology an accepted and useful part of our everyday lives.

At Battelle, perhaps the best example is how their scientists took a concept for copying documents and moved it from basic research to commercialization. The final product, now known as Xerox, has been quite successful.

Southwest Research Institute has been doing much to improve automobile engine efficiency and the efficiencies of fuels and lubricants.

As these examples illustrate, the capability to bring a variety of disciplines to bear is a special strength.

From the standpoint of U.S. government mission agencies, that capability is important. Not only do we provide scientific and technical competence on an "as-needed" basis--thereby reducing the need for permanent government staff, but then we also provide a broader, more complete view of the societal and business impact of a technical issue.

With that introductory positioning, let me address some specific aspects of our involvement in mission agency research programs.

The manner in which we participate is quite broad. Projects are initiated through:

- competitive contracts, as with any industrial contractor in the procurement process
- grants, won in response to general program announcements
- technical and engineering support contracts, which are a subset of the competitive contract process
- cooperative agreements, which require cost sharing with federally funded research and development centers (FFRDC) that are wholly captive to specific mission requirements and
- unsolicited proposals.

In the past, the various competitors for mission agency research dollars were more compartmentalized. Industry used its manufacturing and productive skills in performing specific contracts which were at the application end of the technology spectrum. Universities tended to the opposite end, focusing on basic research. Other participants clustered around either research or commercialization.

Not-for-profit research institutes covered the entire spectrum, understanding the complete process, but accounting for a very small part of the total research spending by the Federal government. While more industry and business-oriented than universities, we have been, and are, more academic than commercial research laboratories.

Today, as economic pressure increases, corporations and universities are reaching out to new areas for funding. The Industrial Research Institute, for instance, which represents the interests of industry here in Washington, is conducting a study on how the results from federally supported research can best be channeled to the private sector. The competition for research funding has grown and with it the demand for efficiency. This places increased emphasis on the management of research which is a quality that lies at the center of not-for-profit research institutes.

Within the government, competition for funding has also increased. There is also a demand for more efficient utilization

of each research dollar. As a result, the focus of the mission agencies has become more and more specific. Recent changes in procurement, such as the Competition in Contracting Act, have had an adverse impact on research in some ways. While drafters of the Act did not intend that research should be procured on the basis of price rather than scientific expertise, the thrust to increase competition has produced that result to a noticeable extent. Furthermore, despite exceptions to the Act for the procurement of unsolicited research proposals, the agencies are contracting for fewer of those innovative researcher-originated ideas. In the short term, agencies may find some economic relief from this situation, but in the long run, it will hurt U.S. science. This is not to say that there aren't efficiencies to be gained in the funding process, or that all research should be done "sole source". However, funding research should be viewed differently from procuring a product, as it usually is in industry.

Another change that has come about in the search for a more efficient use of research dollars is that the number of competitive procurements is going down while increasing in size. Today, the dollar value is higher and the scope of procurements is much broader. This broader scope almost demands the formation of team relationships between program participants. Naturally, that shows up in higher bidding costs to cover more complicated project coordination. The effect of this is to actually raise the cost of research, to get less science for the dollars.

What is needed? Before addressing that, let me say that the basic system under which we work with the mission agencies is a good one. Proposal solicitation is orderly. The review systems most agencies have for research grants work well. In contracts, reporting schedules are adequate. One might question the increasing complexity of safety and quality assurance regulations, since they tend to add to the price of research and are unnecessary for good researchers. They are intended to prevent bad data but raise project cost.

Long range research planning input to the mission agencies is rather informal and has always been seen as a part of the continuing dialog between researchers and agency personnel. However, we need a better forum for the setting of technology priorities. While many of the not-for-profits' management and experts participate on boards and commissions, presenting new ideas and concepts, the discussion is informal in many ways. It would be useful to have a more formal research information and planning structure--not to rigidly assign tasks--but to uncover new ideas, to provide input.

While the not-for-profit institutes account for a very small--less than 2%--part of the overall research and development activities of the United States, the impact over the years has far outweighed their size. In the years ahead, we will continue to cover the technological spectrum from laboratory to marketplace, applying a true multidisciplinary capability to the solution of problems. We will also continue to provide a unique training ground, an environment where young scientists can see the interplay of theory and practice.

I am forcefully reminded of how good we are at that every time a corporate raider hires away some of our bright young people. We fulfill an important post-doctoral and post-graduate training function. Additionally, we have a large number of graduate students from nearby universities working at SRI.

In the RAND Corporation report "Interdisciplinary Policy Research in Independent Research Centers", Walter Baer judged interdisciplinary research by five criteria:

(1) policy orientation--institutional commitment

(2) access to information

(3) independence

(4) scale and continuity of effort, and skilled personnel

(5) incentives for performance.

Using a scale from 0-10, with 10 the highest, Baer found that independent research centers rated highest, followed by industry, government and universities.

These criteria are still valid. Industry and universities have both moved towards the center of the technology spectrum because of financial pressure and have both been making themselves more visible in the process. The not-for-profit research institutes, facing similar pressure, can no longer remain in the background. Because we fall in the middle, Congress and the mission agencies often overlook us in legislation and in the promulgation of regulations. Yet, the not-for-profit research institute has a unique value in meeting the changing needs of society.

One observer summed it up very well when he said, "The not-for-profit research institute is better able than a university department to generate knowledge which is reliable and timely or requires the coordinated and protracted work of many people. Perhaps it would be better to say that institutes have found new ways of organizing--not knowledge, but professional people."

Thank you.

Mr. VOLKMER (acting chairman). Thank you very much, Mr. Miller.

Dr. Levy.

[A biographical sketch of Dr. Levy follows:]

DR. EUGENE H. LEVY

Born May 6, 1944 in New York City. Public school in New York City and Fair Lawn, N.J., graduating high school in 1962. Bachelor of Arts, high honors in Physics, Rutgers University, 1966. Doctor of Philosophy, Physics, University of Chicago in 1971.

Married to Margaret Lyle Rader, 1967; 3 children. Residing in Tucson, Arizona since 1975.

Present position: Professor & Head, Planetary Sciences Dept., Director of Lunar and Planetary Lab., University of Arizona. Also Faculty of Appl. Math. Teaches graduate and undergraduate courses.

Research and Publications: Theoretical cosmical physics, planetary physics, solar and space physics, magnetohydrodynamics. Generation and behavior of magnetic fields in natural bodies, including Earth, the Sun, and planets; origin of geomagnetic reversal; theory of cosmic rays; formation of the solar system. Techniques for the discovery and study of other planetary systems.

Previous Positions: Res. Physicist, Kodak Physics Lab., 1966; Teaching Asst., Dept. of Physics, Univ., of Chicago, 1966–1969; Res. Asst., Dept. of Physics—Enrico Fermi Inst., Univ. of Chicago, 1969–1971; Fellow, Dept. of Physics and Astronomy, Univ. of Maryland, 1971–1973; Asst. Prof., Physics & Astrophysics, Bartol Res. Foundation, Franklin Inst., 1973–1975.

Awards, Honors, Societies: NASA Fellow, Univ. of Chicago, 1966–1969; Theoretical Physics Fellow, Univ. of Maryland, 1971–1973; Phi Beta Kappa; Sigma Xi; Am. Astron. Soc.; Am. Phys. Soc.; Geophys. Un.; Int'l. Astron. Un. NASA Distinguished Public Service Medal, 1983. Res. grants from NSF & NASA.

Other Activities: Consulting and adv. panels, including member of Nat'l Acad. of Sci. Space Sci. Bd., Chair of Comm. on Planet and Lunar Enpl.; NASA Space Sci. Adv. Subcomm. & Solar Sys. Expl. Comm., 1980–1983; Comet Halley Sci. Work. Grp., 1977; Comet Mission Rev. Comm., 1980; U.S. Delegate to U.S.-Soviet Joint Work. Grp. on Near-Earth Space, Moon, & Planets; Head of U.S. Delegation to Nat'l Acad. of Sci.-European Sci. Found. Joint Working Group on Coop. in Planet. Expl., 1982–83; NASA Solar Sys. Expl. Management Council 1983–85; Congressional OTA Panel on U.S.-Soviet Sci. Coop.; NASA Space and Earth Sci. Adv. Comm., 1985–88. Scientific Consult., Rockwell Int'l. Corp. 1980. Distinguished Visiting Scientist, Jet Propulsion Lab. of the Calif. Inst. of Tech.

Address & Telephone: Office: Lunar and Planetary Laboratory, University of Arizona, Tucson, AZ 85721 [(602) 621–6962].

STATEMENT OF DR. EUGENE H. LEVY, PROFESSOR AND HEAD, DEPARTMENT OF PLANETARY SCIENCES; AND DIRECTOR, LUNAR AND PLANETARY LABORATORY, UNIVERSITY OF ARIZONA, TUCSON, AZ

Dr. LEVY. Mr. Chairman and members of the committee, I am pleased to be invited before this committee to discuss with you matters of national science policy. I believe that our examination of U.S. science policy is indeed timely. Vigorous scientific research is crucial to our national interest. And I do not believe that present policies are sustaining many U.S. scientific activities and capabilities in a way that meets the long-term interests and needs of our Nation.

My remarks this morning are based on my experience as a research scientist over some 15 years and as a university department head and director of a major research laboratory devoted to the space and planetary sciences.

The role of the universities and the mission agencies—let me begin by making some remarks about the special role of universi-

ties in our Nation's overall scientific research structure. I believe that the universities play an especially valuable role in U.S. science. The scientific enterprise involves several activities.

First, of course, is the conduct of research itself—the generation of new knowledge and understanding, and the invention of techniques to utilize and exploit knowledge.

Second is the propagation of knowledge throughout the society. The teaching of relatively large numbers of technically trained individuals who may do little or no research but who apply existing knowledge to the solution of society's myriad problems.

Third is the organization, preservation, and transmission of accumulated knowledge from generation to generation.

And fourth is the training and apprenticeship of the next generation of research scientists, those who will carry on into the future and generate yet more new knowledge and understanding.

Uniquely among the research institutions in U.S. science, the universities carry out all of these crucial functions. Moreover, the universities' contribution is more than the mere sum of these parts. There are symbiotic effects. I believe that the assembly of these four important activities in universities generally results in each of the functions being carried out more effectively than it might be in isolation.

I do not want to minimize the contributions of either the national laboratories, or applied and industrial research centers. However, in my view, the combination of research and teaching, the organization and preservation of knowledge, and the apprenticeship of young scientists that occurs daily in our universities provides the primary source of vigor and success in U.S. science.

I raise this issue early in my remarks to make the point that I believe that the health of the university research enterprise is essential to the health of U.S. science and technology—and by immediate extension, to the vigor and competitiveness of our Nation as a whole. It follows, therefore, that the health of the university research and education endeavor in this Nation must be a central concern of any wise national science policy. And the health and vigor of university research and education must be a central concern of all Federal science agencies—the mission agencies and the nonmission agencies alike.

Alas, it is my strong impression that this has rarely been the case in recent years. Indeed, on several occasions I have been told by congressional staffers as well as by agency officials, that the health of university research, per se, is not a concern of NASA, that it is not part of the NASA mission. I am less familiar with the other mission agencies, but I assume that similar attitudes prevail in those also. I cannot emphasize enough, as a scientist and as a citizen of our Nation, how shortsighted an approach I believe this is to the future of our society.

Of course, such shortsightedness has not always prevailed. In the early 1960's, our Nation undertook to ensure a scientific infrastructure of research facilities and research personnel, along with a vigorous program of scientific projects. During the time when the National Aeronautics and Space Administration was being founded, efforts were exerted by the Federal Government to enable a steady pace of scientific project parts, to encourage the training of a large

and effective cadre of young scientists, and to provide adequate modern scientific facilities and equipment for the conduct of research. I think it is few of today's leading space scientists who were untouched by those wise programs. Indeed, speaking for myself, I received my graduate education with a federally-sponsored fellowship and I have spent almost my entire career working in research facilities constructed under Federal programs more than 20 years ago. I believe that the past 20 years have been remarkable for the advances in science and technology paced by the United States. I also believe that this rapid pace of advance is due in large measure to the enlightened Federal science policies of the 1960's.

To the large extent, I believe that we are still living off the fruits of those enlightened policies of the early 1960's. What I mean is that those enlightened policies of the early 1960's. What I mean is that: U.S. research programs are still housed in the same physical plants, which are in many instances becoming inadequate; it is widely recognized that research equipment in the United States is growing increasingly obsolete, and too few of the scientists who have come of age during the past 10 to 15 years, after the policies changed, have been able to build research careers because of the lack of adequate research opportunities.

It seems to me that this situation—with the Nation's facilities continuing to age, with U.S. scientific equipment falling further into obsolescence, and with the presently active cohort of scientists aging while insufficient numbers of younger colleagues follow them in stably established careers with adequate research opportunities—is very deleterious to our national interest.

Recently there have been some small steps in the right direction, giving evidence at least that the problem is starting to be recognized. Last year NASA instituted a very small program of research fellowships for university graduate students. This indicates some recognition of a critical need to encourage young people into productive scientific careers. Unfortunately, I am not aware that any funds were appropriated to support this program, and I believe that, as a result, the funding involved a set-aside from other programs. To the extent that this fellowship program was funded by setting aside moneys from elsewhere in the basic research program, this is no solution at all. I do not believe that moving funds around within the already-strapped basic research programs is a useful response to the funding of fellowships; nor do I believe that such set-asides would be a useful response to the other problems of rebuilding the U.S. scientific infrastructure.

I also regard the small instrumentation-refurbishment program recently started by the Department of Defense as a step in the right direction. The vast oversubscription of this program is another piece of evidence that research equipment shortage and obsolescence is becoming a crisis in the United States. So far, however, no program has been brought forward that is of sufficient scope to make a big impact on the Nation's overall needs in research equipment.

NASA's science program, which runs at about 15–20 percent of its total budget, consists of several components which can be usefully identified. These include construction and operation of space missions and associated activities—the largest part, by far, of the

science budget—advanced technology development for future missions, and basic research activities. Much of the direct funding for research in our Nation's universities come from the last category: The so-called basic research and analysis activities; the largest part of NASA's science budget, the actual development, construction, and operation of spacecraft projects, goes largely to industry and national laboratories.

The relationship between basic space science research and the spacecraft missions is a close one. On the one hand, much of the basic research is intended to be in support of the objectives of the spacecraft program. On the other hand, the spacecraft program is largely responsive to the goals established by the scientific community as a result of the continuing basic research activities. Formally these goals, and the plans to realize them, are set through an extensive advisory process involving a broad cross section of the Nation's scientists, and reporting under the aegis of either NASA as the in-house committee, or the National Academy of the Sciences, as independent external committees. The Nation's universities are well represented in all of these councils.

Generally speaking, it is my view that this approach to the setting of programmatic goals has been effective. Many scientifically excellent and important projects are always in the hopper waiting to be implemented. Indeed, this process has been too effective in that a far larger number of projects than can be accomplished at the present rate are waiting, as potential new starts, a situation which has now been severe for nearly a decade.

One of the truly astonishing examples of the lethargy in the pace of our Nation's new starts in space science projects is the lack of a U.S. spacecraft mission to Comet Halley. The failure of the United States to respond to the appearance of Comet Halley—an event of not only deep scientific importance, but also of social and historical significance—must denote a turning point in our perception of U.S. scientific and international leadership.

A considerable amount of detailed planning for a mission to Comet Halley, was done throughout the late 1970's. Initial plans were for a mission far more capable than any within the reach of Europe or the Soviet Union. Yet here we are, just months before Comet Halley passes through the inner solar system: Japan has a modest spacecraft on its way to fly near Comet Halley; the European space agency is sending a space probe deep into the heart of the comet; and a literal parade of international scientists is lined up under the banner of the Soviet Union, with instruments on two Soviet spacecraft headed to encounter the comet.

The United States, in the meantime, sits on its figurative hands. For the most part, U.S. scientists in universities and elsewhere, are excluded from the main action of a major scientific challenge and opportunity. Fortunately, there are other comet opportunities. NASA has plans for an encounter with Comet Wild 2. But it now looks as if we may continue to sit on our national hands and pass up this one also.

Although these last several sentences about the U.S. Comet Halley debacle seem like a digression from my main point, they are in fact not a digression. All components of the space science program, space flight missions, advanced technology development, and

the so-called research and analysis activities are essential to vigor of space science in the Nation and the Nation's universities.

The relatively small number of spacecraft flight opportunities during the past decade has had a large effect on the profile of the space science experimental community. There is a startling absence of young scientists age 30 to 40 who have been able to establish space experimental research groups in the past decade. I can point to at least one important area of experimental space science in which practically the entire U.S. population of experienced practitioners will retire within the next few years. This is entirely a result of the absence of space flight opportunities.

I am to address here certain detailed, structural aspects of the mission agencies programs as they relate to universities. There are many important secondary issues with which I could deal. For example, the deluge of paperwork and niggling bureaucratic detail which encumbers so many activities and accomplishes nothing. However, I do not believe that these detailed structural questions can be isolated from the overall level and vigor of U.S. research programs in space. The fundamental structural problems in university space research and space science related national infrastructure derive from the diminished vigor of our national programs. In order to solve these problems will require:

An increase in the pace of space flight projects, both major ambitious projects and smaller projects that be done rapidly and relatively inexpensively. These would engender important fundamental science and would provide a path into experimental space science for young investigators.

An increase in the basic research and analysis programs, refurbishment of research equipment, and research and development on new experimental techniques for space science. This would rebuild and invigorate the university research and advanced training programs, and it would also encourage and support young scientists early in their careers.

Before stopping, I want to relate two personal anecdotal incidents which I believe are representative of the larger problems that I have discussed. Among the most pressing of the issues that face us in grappling with U.S. science policy is, I believe, the question of defining the appropriate level of budgetary support. How, indeed, do we determine whether our programs are adequate to our needs?

Certainly one approach is to ask whether the present program is resulting in the training of sufficient numbers of young American scientists.

Recently, I advertised an opening for a postdoctoral research associate to work in my research program at the University of Arizona. I received a reasonably large number of applications for the position. Most of the qualified applicants were foreign nationals. None of the top three applicants were U.S. citizens. Now, from my prespective as a scientist, this is immaterial. But from the Nation's perspective, this may be indicative of a potential serious problem.

It should not matter that so many of our graduate students are from other nations. After all, the United States was largely populated in this manner, and has a long record of having its population enriched by the peoples of other lands. But things are not

working out so nicely. There are few continuing opportunities for these students in the United States. Indeed, the reason for diminished interest in scientific careers among young American students is the paucity of long-term career opportunities, and this affects foreign nationals who would like to build scientific careers here even more than it affects U.S. citizens. To a large extent, what career opportunities do exist involve classified work in the defense sector and foreign students are largely barred from such positions. So in the end, we are cutting our Nation's future off, both from the vigorous, potentially productive minds among our own young people and from the bright young minds abroad. In my view, it is unwise to continue on this course.

One final personal remark builds on this point. Nine years ago I was appointed to my first high-level national advisory committee for space science. At the time I, and a few of my colleagues, were the youngest scientists in the Nation serving on such space science advisory committees. Last summer, at a meeting of a large number of advisory panels for space science, involving some 100 scientists under the auspices of the National Academy of Sciences, I noticed that I still seemed to be practically the youngest in attendance. An informal survey by several colleagues nearly confirmed that impression. There were, in fact, one or two slightly younger panelists present, but only by a couple of years.

These are anecdotes. But they point up the fact that there is a paucity of young scientists beginning their careers in a number of important scientific disciplines—not an absence, mind you, but a paucity to a degree that I believe is alarming. A national science policy should ensure that our society's needs are met with respect to the production, propagation, and utilization of knowledge, and with respect to the production of new cadre's of young scientist for the future. These are, in my view, the goals of an effective relationship between the science agencies and the universities. My experience suggests to me that present policies are deficient in both respects.

Unfortunately, there are no unequivocal measures against which we can judge these things. Decisions in these areas of policy require a measure of sense and wisdom. We either judge wisely and benefit, or we judge unwisely and suffer for it in the long run. I am encouraged that this committee is examining the issues.

Thank you for your attention. I will be glad to discuss these matters further or to try to respond to other questions you may have.

[The prepared statement of Dr. Levy follows:]

Remarks to the

COMMITTEE ON SCIENCE AND TECHNOLOGY
UNITED STATES HOUSE OF REPRESENTATIVES

NATIONAL SCIENCE POLICY HEARINGS
Science in the Mission Agencies:
Relationships with Extramural Researchers
The Universities

October 4, 1985

Eugene H. Levy, Professor
Head, Department of Planetary Sciences
Director, Lunar and Planetary Laboratory

University of Arizona
Tucson, Arizona 85721

Statement of Eugene H. Levy

Mr. Chairman and members of the committee:

I am pleased to be invited before this committee to discuss with you matters of national science policy. I believe that your examination of U.S. science policy is indeed timely. Vigorous scientific research is crucial to our national interest. And I do not believe that present policies are sustaining many U.S. scientific activities and capabilities in a way that meets the long-term interests and needs of our nation.

My remarks this morning are based on my experience as a research scientist over some 15 years and as a university department head and director of a major research laboratory devoted to the space and planetary sciences.

I have been asked to focus on the role of mission agencies in the conduct of U.S. science in universities. In terms of dealing with mission agencies, my own experience--as a scientist and as a department head and laboratory director--has been greatest with the National Aeronautics and Space Administration. The National Science Foundation is another agency with which I have had considerable experience. To the extent that my remarks refer to specific experience, they will be based largely on my experience with NASA. In addition, because I am speaking in terms of my experience, rather than on the basis of detailed surveys or statistical research, I will relate my impressions, derived largely from what I see happening in the space sciences.

The Role of the Universities & The Mission Agencies

Let me begin by making some remarks about the special role of universities in our nation's overall scientific research structure. I believe that the universities play an especially valuable role in U.S. science. The scientific enterprise involves several activities:

-- First, of course, is the conduct of research itself: the generation of new knowledge and understanding, and the invention of techniques to utilize and exploit knowledge.

-- Second is the propagation of knowledge throughout the society: the teaching of relatively large numbers of technically trained individuals who may do little or no research but who apply existing knowledge to the solution of society's myriad problems.
-- Third is the organization, preservation, and transmission of accumulated knowledge from generation to generation.
-- And fourth is the training and apprenticeship of the next generation of research scientists, those who will carry on into the future and generate yet more new knowledge and understanding.

Uniquely among the research institutions in U.S. science, the universities carry out all of these crucial functions. Moreover, the universities' contribution is more than the mere sum of these parts. There are symbiotic effects. I believe that the assembly these four important activities in universities generally results in each of the functions being carried out more effectively than it might be in isolation.

I do not want to minimize the contributions of either the national laboratories, or applied and industrial research centers. However, in my view, the combination of research and teaching, the organization and preservation of knowledge, and the apprenticeship of young scientists that occurs daily in our universities provides the primary source of vigor and success in U.S. science.

I raise this issue early in my remarks to make the point that I believe that the health of the university research enterprise is essential to the health of U.S. science and technology--and, by immediate extension, to the vigor and competitiveness of our nation as a whole. It follows, therefore, that the health of the university research and education endeavor in this nation must be a central concern of any wise national science policy. And the health and vigor of university research and education must be a central concern of all federal science agencies--the mission agencies and the non-mission agencies alike.

Alas, it is my strong impression that this has rarely been the case in recent years. Indeed, on several occasions I have been told--by congressional staffers as well as by agency officials--that the health of university research, per se, is not a concern of NASA: that it is not part of the NASA mission. I am less familiar with other mission agencies, but I

assume that similar attitudes prevail in those also. I cannot emphasize enough, as a scientist and as a citizen of our nation, how short sighted an approach I believe this is to the future of our society.

Of course, such short sightedness has not always prevailed. In the early 1960's, our nation undertook to ensure a scientific infrastructure of research facilities and research personnel, along with a vigorous program of scientific projects. During the time when the National Aeronautics and Space Administration was being founded, efforts were exerted by the federal government to enable a steady pace of scientific project starts, to encourage the training of a large and effective cadre of young scientists, and to provide adequate modern scientific facilities and equipment for the conduct of research. I think it is accurate to say that few of today's leading space scientists were untouched by those wise programs. Indeed, speaking for myself, I received my graduate education with a federally-sponsored fellowship and I have spent almost my entire career working in research facilities constructed under federal programs more than 20 years ago. I believe that the past twenty years have been remarkable for the advances in science and technology paced by the United States. I also believe that this rapid pace of advance is due in large measure to the enlightened federal science policies of the 1960's.

To a large extent, I believe that we are still living off the fruits of those enlightened policies of the early 1960's. What I mean is that:

-- U.S. research programs are still housed in the same physical plants, which are in many instances becoming inadequate,

-- it is widely recognized that research equipment in the United States is growing increasingly obsolete, and

-- too few of the scientist who have come of age during the past ten to fifteen years, after the policies changed, have been able to build research careers because of the lack of adequate research opportunities.

It seems to me that this situation--with the nation's facilities continuing to age, with U.S. scientific equipment falling further into obsolescence, and with the presently active cohort of scientists aging while insufficient numbers of younger colleagues follow them in stably established

careers with adequate research opportunities--is very deleterious to our national interest.

Recently, there have been some small steps in the right direction, giving evidence at least that the problem is starting to be recognized. Last year NASA instituted a very small program of research fellowships for university graduate students. This indicates some recognition of a critical need to encourage young people into productive scientific careers. Unfortunately, I am not aware that any funds were appropriated to support this program, and I believe that, as a result, the funding involved a "set-aside" from other programs. To the extent that this fellowship program was funded by setting aside monies from elsewhere in the basic research program, this is no solution at all. I do not believe that moving funds around within the already-strapped basic research programs is a useful response to the funding of fellowships; nor do I believe that such "set-asides" would be a useful response to the other problems of rebuilding the U.S. scientific infrastructure.

I also regard the small instrumentation-refurbishment program recently started by the Department of Defense as a step in the right direction. The vast oversubscription of this program is another piece of evidence that research equipment shortage and obsolescence is becoming a crisis in the United States. So far, however, no program has been brought forward that is of sufficient scope to make a big impact on the nation's overall needs in research equipment.

Components of a Productive Relationship

NASA's science program, which runs at about 15-20% of its total budget, consists of several components which can be usefully identified. These include construction and operation of space missions and associated activities (the largest part, by far, of the science budget), advanced technology development for future missions, and basic research activities. Much of the direct funding for research in our nation's universities comes from the last category: the so-called basic research and analysis activities; the largest part of NASA's science budget, the actual development, construction, and operation of spacecraft projects, goes largely to industry and national laboratories.

The relationship between basic space-science research and the spacecraft missions is a close one. On the one hand, much of the basic research is intended to be in support of the objectives of the spacecraft program. On the other hand, the spacecraft program is largely responsive to the goals established by the scientific community as a result of the continuing basic research activities. Formally these goals, and the plans to realize them, are set through an extensive advisory process involving a broad cross section of the nation's scientists--and reporting under the aegis of either NASA as in-house committees, or the National Academy of the Sciences as independent, external committees. The nation's universities are well represented in all of these councils.

Generally speaking, it is my view that this approach to the setting of programmatic goals has been effective. Many scientifically excellent and important projects are always in the hopper waiting to be implemented. Indeed, this process has been too effective in that a far larger number of projects than can be accomplished at the present rate are waiting, as potential new starts, a situation which has now been severe for nearly a decade.

One of the truly astonishing examples of the lethargy in the pace of our nation's new starts in space science projects is the lack of a U.S. spacecraft mission to Comet Halley. The failure of the United States to respond to the appearance of Comet Halley--an event of not only deep scientific importance, but also of social and historical significance--must denote a turning point in our perception of the United States' scientific and international leadership.

A considerable amount of detailed planning for a mission to Comet Halley was done throughout the late 1970's. Initial plans were for a mission far more capable than any within the reach of Europe or the Soviet Union. Yet here we are, just months before Comet Halley passes through the inner solar system:

-- Japan has a modest spacecraft on its way to fly near Comet Halley.

-- The European Space Agency is sending a space probe deep into the heart of the comet.

-- A literal parade of international scientists is lined up under the

banner of the Soviet Union, with instruments on two Soviet spacecraft headed to encounter the comet.

The United States, in the meantime, sits on its figurative hands. For the most part, U.S. scientists--in universities and elsewhere--are excluded from the main action of a major scientific challenge and opportunity. Fortunately, there are other comet opportunities. NASA has plans for an encounter with Comet Wild 2. But it now looks as if we may continue to sit on our national hands and pass up this one also.

Although these last several sentences about the U.S. Comet Halley debacle seem like a digression from my main point, they are, in fact, not a digression. All components of the space-science program--spacecraft flight missions, advanced technology development, and the so-called research & analysis activities--are essential to vigor of space science in the nation and in the nation's universities.

The relatively small number of spacecraft flight opportunities during the past decade has had a large effect on the profile of the space-science experimental community. There is a startling absence of young scientists--ages 30 to 40--who have been able to establish space experimental research groups in the past decade. I can point to at least one important area of experimental space science in which practically the entire U.S. population of experienced practitioners will retire within the next few years. This is entirely a result of the absence spaceflight opportunities.

I am to address here certain detailed, structural aspects of the mission-agency programs as they relate to universities. There are many important secondary issues with which I could deal--for example, the deluge of paperwork and niggling bureaucratic detail which encumbers so many activities and accomplishes nothing. However, I do not believed that these detailed structural questions can be isolated from the overall level and vigor of U.S. research programs in space. The fundamental structural problems in university space research and space-science-related national infrastructure derive from the diminished vigor of our national programs. In order to solve these problems will require:

-- An increase in the pace of spaceflight projects, both major ambitious projects and smaller projects that can be done rapidly

-- An increase in the basic research and analysis programs, refurbishment of research equipment, and research and development on new experimental techniques for space science. This would rebuild and invigorate the university research and advanced training programs, and it would also encourage and support young scientists early in their careers.

* * *

Before stopping, I want to relate two personal anecdotal incidents which I believe are representative of the larger problems that I have discussed. Among the most pressing of the issues that face us in grappling with U.S. science policy, is, I believe, the question of defining the appropriate level of budgetary support. How, indeed, do we determine whether our programs are adequate to our needs?

Certainly one approach is to ask whether the present program is resulting in the training of sufficient numbers of young American scientists.

Recently, I advertised an opening for a postdoctoral research associate to work in my research program at the University of Arizona. I received a reasonably large number of applications for the position; most of the qualified applicants were foreign nationals. None of the top three applicants were United States citizens. Now, from my perspective as a scientist, this is immaterial. But from the nation's perspective this may be indicative of a potentially serious problem.

It should not matter that so many of our graduate students are from other nations. After all the United States was largely populated in this manner, and has a long record of having its population enriched by the peoples of other lands. But things are not working out so nicely. There are few continuing opportunities for these students in the United States. Indeed, the reason for diminished interest in scientific careers among young American students is the paucity of long-term career opportunities;

and this affects foreign national who would like to build scientific careers here even more than it affects U.S. citizens. To a large extent, what career opportunities do exist involve classified work in the defense sector; and foreign students are largely barred from such positions. So, in the end, we are cutting our nation's future off, both from the vigorous, potentially productive minds among our own young people and from the bright young minds abroad. In my view, it is unwise to continue on this course.

One final personal remark builds on this point. Nine years ago I was appointed to my first high-level national advisory committee for space science. At the time I, and a few of my colleagues, were the youngest scientists in the nation serving on such space-science advisory committees. Last summer, at a meeting of a large number of advisory panels for space science--involving some 100 scientists under the auspices of the National Academy of Sciences--I noticed that I still seemed to be practically the youngest in attendance. An informal survey by several colleagues nearly confirmed that impression. There were, in fact, one or two slightly younger panelists present, but only by a couple of years.

These are anecdotes. But they point up the fact that there is a paucity of young scientists beginning their careers in a number of important scientific disciplines--not an absence, mind you, but a paucity to a degree that I believe is alarming. A national science policy should ensure that our society's needs are met with respect to the production, propagation, and utilization of knowledge, and with respect to the production of new cadre's of young scientists for the future. These are, in my view, the goals of an effective relationship between the science agencies and the universities. My experience suggests to me that present policies are deficient in both respects.

Unfortunately, there are no unequivocal measures against which we can judge these things. Decisions in these areas of policy require a measure of sense and wisdom. We either judge wisely and benefit, or we judge unwisely and suffer for it in the long run. I am encouraged that this committee is examining the issues.

Thank you for your attention. I will be glad to discuss these matters further or to try to respond to other questions you may have.

Mr. VOLKMER. Thank you very much, Dr. Levy.
Dr. Ebel.
[A biographical sketch of Dr. Ebel and Mr. Dummer follows:]

DR. MARVIN EMERSON EBEL

Name: Marvin Emerson Ebel. Birth Place & Date: Waterloo, Iowa, September 23, 1930.

Address: Office: 328 Bascom, University of Wisconsin, Madison, WI 53706, 608 262-1044. Home: 910 Hampshire Place, Madison, WI 53711, 608 271-6254.

Marital Status: Married, 1960, to Barbara Ann Schuck, 4 children.

Education: 1946-47, Iowa State Teachers College; 1950 B.S., Iowa State College; 1952, M.S., Iowa State College; 1953, Ph.D., Iowa State College.

Experience: 1949-53, Teaching Assistant, Iowa State College; 1954-56, Instructor, Yale; 1956-57, Assistant Professor, Yale; 1957-59, Assistant Professor, Wisconsin; 1959-65, Associate Professor, Wisconsin; 1965- Professor, Wisconsin-Madison; 1973-75, Chairman, Physics Department; 1976- Associate Dean, Graduate School.

Fellowships: 1952-53, Research Corporation Fellow; 1953-54, NSF Postdoctoral Fellow; Niels Bohr Institute, Copenhagen; 1957-62, Alfred P. Sloan Foundation Fellow.

Consultant: 1959-73, Los Alamos Scientific Lab; 1962-64, IDA.

Memberships: AAUP; Phi Kappa Phi; Fellow, American Physical Society; Sigma, Xi.

Committees: 1981-82 University: Graduate School Administrative; Research Committee; Knapp Center Advisory; Graduate Assistant Stipends (Ch.); Physical Sciences Lab Advisory; Math. Research Center Advisory; Academic Computing Advisory (Vice-Coordinator of Computing); Faculty Advisory Committee on A-21; Academic Staff Area Review Committee (Administrative/Student Services/Library); Ad Hoc Committee on Research Opportunities; U.W. System Task Force on Conflict of Interest Rules.

Other Professional: Argonne Universities Association (U.W. delegate); Universities Research Association (U.W. delegate); CIC Research Officers (Ch.); Grant and Contract Policies Subcommittee of Council on Governmental Relations; AAU Task Force Effort Reporting.

GEORGE H. DUMMER

Director, Office of Sponsored Programs, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139. Home Address: 10 Princeton Road, Wellesley, Massachusetts 02181. Married to: Former Mary Martha Goodwin, Oil City, Pa. Children: David, 17; Steven, 15; Douglas, 13.

Educational background: Harvard College, B.S., 1948; Harvard Law School, J.D. 1949.

Military Service: U.S. Navy, 1950-1952: USS *Philip* (DDE498), Gunnery Officer; Pearl Harbor, Korea, Formosa, with 7th Fleet.

Professional experience (Pre-MIT): Ford Motor Company, Somerville Plant, 1952-1954, Public Relations Representative; University of California Scientific Laboratory, Los Alamos, New Mexico, 1955-1958: Group Leader, Personnel Relations.

Massachusetts Institute of Technology: Personnel Officer for Professional Personnel, 1958-1960; Office of Sponsored Programs (formerly Division of Sponsored Research); Assistant, Associate and Administrative Director successively, 1961-1973; Director, 1973 to present.

Outside professional activities (Past and Present): National Council of University Research Administrators; Member of Executive Committee; Chairman of Panels on University-Industry Relationships; Member of Long-Range Planning Committee; Faculty Member, Annual Meeting Workshops; Chairman. Select Committee on University-Industry Relationships (present).

Council on Governmental Relations of the National Association of College and University Business Officers; Chairman of Task Force on Graduate Student Support; Member, Subcommittee on Federal Management Developments; Member, Nominating Committee Member, Subcommittee on Grants and Contracts (present).

Engineering College Research Council of the American Society for Engineering Education; Member, Board of Directors and Secretary.

STATEMENT OF DR. MARVIN E. EBEL, ASSOCIATE DEAN, GRADUATE SCHOOL, UNIVERSITY OF WISCONSIN, MADISON, WI; AND GEORGE H. DUMMER, DIRECTOR, OFFICE OF SPONSORED PROGRAMS, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, CAMBRIDGE MA, ON BEHALF OF THE COUNCIL OF GOVERNMENTAL RELATIONS, WASHINGTON, DC

Dr. EBEL. Mr. Chairman and members of the Task Force on Science Policy, my name is Marvin Ebel and I am Associate Dean of the Graduate School, University of Wisconsin. I have been an active researcher for 30 years, conducting research in high energy physics, supported by the Department of Energy or its predecessor agencies. With me today is George Dummer, Director, Office of Sponsored Programs, Massachusetts Institute of Technology. We are there on behalf of the Council on Governmental Relations, an organization of more than 100 leading research universities. COGR was established to provide information to executive agencies of government with regard to policies, regulations and practices that affect university research. Together, Mr. Dummer and I will give you an idea of procedural matters, some of which assist the conduct of research and ought to be extended or continued Government-wide and some practices that hamper the conduct of research and delay technology transfer and should be discontinued.

I will address: one, cost sharing as an externally imposed constraint on a university's ability to direct its own research spending; two, Government support of university research as both an investment in solving problems critical to energy independence, agriculture, defense and space, and as a key ingredient in the development and training of scientists in these areas; and three, the importance of funding mechanisms and instruments as a means of providing innovative approaches to research.

Mr. Dummer will address how research can be enhanced by: (1) recognizing different classes of grantees and contractors; (2) providing the appropriate climate for research through administrative simplification; (3) and finally, understanding the effect of national security considerations on research at universities.

The first issue which I wish to take up is that of cost sharing on individual research projects, which may be funded either by grants or contracts. Let me make clear at the outset that I am not talking about cost sharing which is implicit in a cooperative agreement, nor am I referring to the sharing of the cost of major research instruments or facilities. In these circumstances it may be entirely appropriate from an institution to share in the cost of a joint research program, or the cost of an instrument or facility, especially when the use may involve projects outside the mission of the agency. What I am concerned about is a practice of expecting universities to bear part of the costs of specific research projects. This expectation is rarely, if ever, a matter of official agency or program policy. Nevertheless, it is all too common to find project officials who want to know what fraction of the costs of the project the university, in contrast to the agency contracting for the research, will bear. This in turn leads faculty to believe that they will be required to secure some university funding for each proposal, if that proposal is to be successful. Those of us in research administration

at universities are then requested to provide an allocation of the university's resources to a project either already supported as part of its mission by a Federal agency, or else proposed in response to an announcement of agency interest in a particular field. It is alleged that this cost sharing is necessary in order to prove institutional interest in the research. Quite frankly, most of us do not have sufficient resources to support many projects which we believe ought to be carried out.

It is not difficult to understand how such practices can arise in times of tight agency and program budgets. Program and project officers are naturally anxious to stretch their budgets as much as is possible and, therefore, encourage principal investigators to seek contributed funds from the institution wherever possible.

Although the motive of this "informal" cost sharing requirement is easy to understand, the practice is nonetheless injurious to the research enterprise. It must be understood that the funds supplied by universities for this purpose are not new money; they instead have been diverted from the support of other research programs. The total amount of research performed will not be increased; it will only be channeled in particular ways. Any such externally imposed constraint on a university's ability to direct its own research spending leads to a less than optimal use of that institution's resources. Although limited, these resources can be enormously useful to provide insurance so that projects may not lose momentum and staff when extramural awards are delayed. They can also provide needed funds to start new investigators with facilities, equipment and support staff when extramural awards are delayed. They can also provide needed funds to start new investigators with facilities, equipment and support staff until they are able to compete successfully for outside support. In this way, a pool of talent for addressing scientific problems of national interest can be maintained and increased. In such ways the program of the agency may be advanced more than it would be by simply adding the same amount of money on top of an existing grant or contract. It is not just a matter of equity, it is also a matter of efficiency.

There are other ways in which this practice is also undesirable from the standpoint of the agency. Inevitably, the infusion of other funds leads to a dilution of the agency's right to set the goals of the research. More directly, the degree of cost sharing promised by an institution can become a criterion determining which of several competing proposals is funded. On many occasions, institutions may find it appropriate to share in the cost of a project funded primarily by one or another Federal agency. There is no problem when this is the result of the analysis and determination by the institution that this is the best way to use its resources. It is objectionable when this support occurs not because the project has won institutional support based on its own merits, but rather because a need to somehow match Federal expenditures on that individual project. Many institutions have programs for competitive research grants of university funds. A project is not, and should not be ineligible simply because it is receiving Federal support. On the other hand, it should not receive enhanced priority solely because it receives such support. Such forced cost sharing can be very destruc-

tive of the cooperation which is essential between Federal agencies and universities if we are to maximize research productivity.

Statutory cost sharing has become unduly burdensome. A large administrative network has grown up over the 19 years that statutory cost sharing has been in effect. The network is necessary to document rather precisely the apportionment of such costs to research and instruction so as to satisfy Government auditors. This artificial distinction of costs discourages universities from making voluntary contributions.

The second issue which I wish to address is that of the support of graduate students working in areas of interest to the various mission agencies. This committee has already heard testimony regarding some potentially critical problems in the supply of scientists and engineers in the next 10 years. Any shortage in the available pool of technical and scientific personnel will inevitably interfere with the ability of the Nation to carry out critical research in the areas of energy, agriculture, defense and space. I am pleased that the various mission agencies have recognized the importance of supporting the development and training of scientists in these areas. Several agencies have initiated fellowship programs to help assure the Nation of an adequate supply of trained scientists and engineers, in particular critical areas.

A far larger source of graduate student support comes in the form of research assistantships on projects funded by Federal grants and contracts. Graduate training demands research experience. Without exposure to modern techniques, instrumentation and problems, that training is sterile. Correspondingly, research programs need not only the hands, but also the fresh approach and ideas which students can provide. It is reassuring that this relationship seems to be accepted now by the granting agencies. There is to my knowledge little disagreement at this time between universities and Federal agencies regarding the propriety of using grant and contract funds to provide this student support when the students are actually working on the projects. I merely wish to emphasize the importance of continuing this support. It is in the best interests of both the Federal Government and universities, indeed of science and technology as a whole.

One question raised in the statement of purpose for this hearing relates to the effectiveness of different funding mechanisms and instruments. I would like to comment briefly on these mechanisms from my own perspective, although I have drawn heavily for background on the report of the National Commission on Research. Funding mechanisms range from individual research projects, large multi-investigatory research programs, research center, large R&D contracts, which may involve large facilities, and through formula grants to the funding of large national laboratories. Each of these mechanisms plays an important role in the funding of university research, and each may be most appropriate, depending upon the field, nature of facilities needed, and type of problem addressed. The mix of these various mechanisms may differ widely from agency to agency. For example, the Department of Agriculture, unlike the other mission agencies, funds primarily through formula grants.

Nevertheless, each of the mission agencies considered here devotes some fraction of its funds to a competitive, small research project program. The maintenance of such programs seems particularly appropriate since it provides an opportunity for the innovative approaches and thrusts in new directions which frequently comprise the cutting edge of science. In many cases, however, the scale of the experiments or the facilities needed demand the cooperative efforts of a number of scientists and engineers, and large research programs and national facilities and national laboratories required. A prime example of this is the situation in experimental high energy physics. Other examples involve experimental work in fusion, and in many parts of space science. Small seed programs provide the initiative, while large facility grants provide stability continuity and flexibility, which researchers need. This was recognized and formulated as two of the several recommendations of the National Commission on Research. I would not assert that in and of itself a particular funding mechanism is more efficient than another. I do maintain, however, that in certain circumstances a particular mechanisms may be more reasonable, and therefore, more efficient, than another.

The major types of funding instruments are grants, contracts, and cooperative agreements. Cooperative agreements are appropriate when there is a mutuality of goals and control of the research program between the institution and the funding agency. It is not appropriate to use this mechanism to enforce a cost sharing not dictated by the nature of the relationship, as I have discussed previously.

In general, the grant type of funding delegates more authority to the principal investigator and the institution for the management of the project than does a contract. Correspondingly, the agency role is simplified. Universities believe that the grant, an instrument to provide investment in research is well suited for basic research.

The National Commission on Research also recommended assistance as the preferred Government funding mode for research. It is particularly gratifying that the Department of Energy has recently adopted grants as a funding instrument for a number of its programs. Clearly, there will always be research efforts which require the degree of management implicit in a contract. Just as clearly there will continue to be areas of honest disagreement among principal investigators, institutions, and agencies as to whether the degree of control implied by a contract is appropriate.

A reasonable assessment would seem to be that there is increased understanding and concurrence among the parties on this issue. Since the National Commission on Research called upon agencies to be willing to experiment with new concepts as the university-Government relationship evolves, there have been positive responses. This is encouraging.

Thank you.

Mr. VOLKMER. Mr. Dummer.

Mr. DUMMER. Thank you.

Mr. Chairman, members of the task force, my written testimony touches on three aspects of the research grant and contract rela-

tionship between the Federal mission agencies and the universities. I would like now to comment briefly on each of these.

The first is the question of how to preserve in the Federal procurement process the identity of research and development and of the institutions which perform it. This is obviously not a new problem. Almost 40 years ago, Dwight Eisenhower, then General of the Army, in a memorandum in scientific and technological resources, said,

> Within the Army, we must separate responsibility for research and development from the functions of procurement, purchase, storage, and distribution. Our experience during the war and the experience of industry in times of peace indicate the need for such a policy.

Following that memorandum in 1947, leaders from industry, universities, and Government gathered to carry out this policy and made a number of recommendations, two of which are still pertinent today.

First: "Because of the intangible and often unpredictable nature of research and development, the arrangements for research and development contracts must differ from those for procurement of supplies and services."

The second recommendation is the following: "The principles governing the normal operations of organizations capable of performing research and development must be recognized in determining the nature of contractual relationships with such an organization."

It is my belief that the mission agencies which have been the most effective in funding university research have been those which have recognized the differences between the different classes of grantees and contractors and have reflected this in their procurement policies and practices. In some cases, of course, the ability of a mission agency to do this may be either enhanced or inhibited by the manner in which statutory authorities or mandates have been drafted. My written statement cites two examples.

One is the Competition and Contracting Act of 1984 which has just been mentioned. It provides a statutory recognition that the process by which basic research proposals are submitted for scientific and peer review in response to agency announcements of their research interest is in itself a form of competition within the spirit and intent of the act. That act has not been without problems for the universities, but nonetheless, without that particular provision and its prompt implementation by certain of the major mission agencies, I think there could have been a disastrous impact on the orderly funding of basic research, particularly by such agencies as the Office of Naval Research, Air Force Office of Research and Office of Army Research and the Research Office within the Department of Energy.

My second example relates to the regulations proposed in August by the mission agencies with respect to Federal rights and data and copyrights. These regulations fail to differentiate data resulting from university research, from data needed for the competitive procurement or reprocurement of hardware, spare parts and supplies. Subsequently, they could have serious adverse consequences for the university community. They would give Federal agencies broad discretion to control the use and dissemination of technical

data and software by the very universities which had, in fact, generated it.

In addition, the proposed regulations reflect a policy which is incompatible with that adopted by Public Law 96-517. That legislation provided that universities, nonprofit and small businesses, could retain ownership and control over patentable inventions resulting from federally sponsored research in order to commercialize them in the public interest. The effective transfer of technology, however, will not be achieved if patent rights flow to the universities while the right to control the ownership, use and dissemination of technical data in software, which are often intertwined and inseparable from patentable inventions, flows to the Federal agencies. Nonetheless, that would be the case under the proposed regulations, and a number of universities have, in fact, in the last 2 weeks, submitted comments urging that regulations be significantly modified.

I would now like to turn to a second topic, reducing bureaucratic accretion in the administration of research grants and contracts. My point here is that the mission agencies, which have been most effective in funding university research, have also devoted substantial effort to developing simplified grant and contract instruments which recognize the realities of how university research is performed and minimize the phenomena which the National Academy of Sciences Roundtable has characterized as bureaucratic accretion.

My statement cites various aspects of grant and contract administrations which are vulnerable to this phenomenon. It also notes some of the efforts made by mission agencies such as DOE and DID to reverse the process by developing simpler but more effective instruments without sacrificing scientific and project accountability. In addition, some mission agencies are also examining more closely the experience and practice of other agencies, including those of the National Institutes of Health and of the National Science Foundation, which have in recent years taken a number of initiatives in improving research management, some of which are listed in my written statement.

Third and last, I would like to comment on the search for mechanisms by which to balance the requirements of national security against the free flow of scientific communications and, in particular, on the recent evolution of national security controls with respect to university research contracts. Classification is, of course, the best known and the strictest control, but it is so contrary to academic traditions of openness that most universities will not undertake classified research except, perhaps, in separate research centers or separate institutes or in limited circumstances. Nor, presumably, do the Federal agencies wish to classify such research broadly. To quote Assistant Secretary of Defense, Richard Perle, "The price you pay for more classification is to narrow the circle of individuals who have access to information that may be a stimulus to research and development on our part." Consequently, classification does not, as yet, appear to have had a significant impact on university research contracts.

Since 1980, however, export control regulations have received significantly greater attention from the mission agencies and hence, from university contractors. Unlike classified information, techni-

cal data, subject to export regulations, can, of course, be disseminated provided it is not disseminated to foreign nationals or foreign countries without appropriate licensing and within certain requirements.

However, the complexities and the definitional problems of these regulations as they would apply to technical data make them for the most part a rather unsatisfactory method of control with respect to university research activities. In the last few years, therefore, the emphasis appears to have shifted to the definition and control of unclassified but critical technology by the mission agencies themselves. The principal focus at present is probably the Militarily Critical Technologies List maintained by the Department of Defense. The technologies covered by that list, however, are so broad in scope and definition that they appear to cut across large segments of university research.

The Department of Defense activities have been increasingly tempted to place restrictions on the dissemination of information resulting from contracts which appear to involve critical technology or the potential for doing so. A number of groups have, therefore, attempted to develop a workable definition of that segment of critical technology which should be subject to security restrictions in colleges and universities.

The Department of Defense in mid-1984 proposed a draft national policy on the transfer of scientific and technical information. A few months later it announced its own implementation of such a policy. The Department of Defense policy stipulates: one, that classification will be the sole mechanism for control of fundamental research in science and engineering under contracts with colleges and universities; and second, defines fundamental research in terms of the 6.1, 6.2 appropriation categories with limited or rare exceptions. Any restrictions on research not defined as fundamental would, under this policy, be agreed to up front as part of contract negotiations, and universities unable to accept such restrictions could decline the contract at the outset.

I sense some optimism that this DOD formula will, in fact, prove workable provided it is not undermined by conflicting directives within DOD. Its success may also well depend on the extent of which research projects initiated without restrictions are subsequently subjected to controls. If this occurs too frequently or perhaps too abruptly, it will inhibit academic scientists and their research teams from making long-term intellectual commitments to unclassified projects which fall into that grey area of critical technology which may invite controls at a late date.

Mr. Chairman, that concludes my remarks, and thank you.

[The prepared statement of Dr. Abel and Mr. Dummer follows:]

COMMITTEE ON SCIENCE AND TECHNOLOGY
U.S. HOUSE OF REPRESENTATIVES
WASHINGTON, D.C. 20515

SCIENCE POLICY TASK FORCE
TESTIMONY ON
SCIENCE IN THE MISSION AGENCIES

ON BEHALF OF

COUNCIL ON GOVERNMENTAL RELATIONS

BY

Marvin E. Ebel
Associate Dean, Graduate School
University of Wisconsin

George H. Dummer
Director, Office of Sponsored Programs
Massachusetts Institute of Technology

October 4, 1985

Mr. Chairman and members of the Task Force on Science Policy, my name is Marvin Ebel and I am Associate Dean of the Graduate School, University of Wisconsin. I have been an active researcher for 30 years, conducting research in high energy physics, supported by the Department of Energy or its predecessor agencies. With me today is George Dummer, Director, Office of Sponsored Programs, Massachusetts Institute of Technology. We are here on behalf of the Council on Governmental Relations, an organization of more than 100 leading research universities. COGR was established to provide information to executive agencies of government with regard to policies, regulations and practices that affect university research. Together, Mr. Dummer and I will give you an idea of procedural matters, some of which assist the conduct of research and ought to be extended or continued government-wide and some practices that hamper the conduct of research and delay technology transfer and should be discontinued.

I will address (1) cost sharing as an externally imposed constraint on a university's ability to direct its own research spending, (2) government support of university research as both an investment in solving problems critical to energy independence, agriculture, defense and space, and as a key ingredient in the development and training of scientists in these areas, and (3) the importance of funding mechanisms and instruments as a means of providing innovative approaches to research.

Mr. Dummer will address how research can be enhanced by, (1) recognizing different classes of grantees and contractors, (2) providing the appropriate climate for research through administrative simplification, and finally, (3) understanding the effect of national security considerations on research at universities.

Mr. Ebel

COST SHARING

The first issue which I wish to take up is that of cost sharing on individual research projects, which may be funded either by grants or

contracts. Let me make clear at the outset that I am not talking about cost sharing which is implicit in a cooperative agreement, nor am I referring to the sharing of the cost of major research instruments or facilities. In these circumstances it may be entirely appropriate for an institution to share in the cost of a joint research program, or the cost of an instrument or facility, especially when the use may involve projects outside the mission of the agency. What I am concerned about is a practice of expecting universities to bear part of the costs of specific research projects. This expectation is rarely [if ever] a matter of official agency or program policy. Nevertheless, it is all too common to find project officials who want to know what fraction of the costs of the project the university, in contrast to the agency contracting for the research, will bear. This in turn leads faculty to believe that they will be required to secure some university funding for each proposal, if that proposal is to be successful. Those of us in research administration at universities are then requested to provide an allocation of the university's resources to a project either already supported (as part of its mission) by a federal agency, or else proposed in response to an announcement of agency interest in a particular field. It is alleged that this cost sharing is necessary in order to prove institutional interest in the research. Quite frankly, most of us do not have sufficient resources to support many projects which we believe ought to be carried out.

It is not difficult to understand how such practices can arise in times of tight agency and program budgets. Program and project officers are naturally anxious to stretch their budgets as much as is possible and, therefore, encourage principal investigators to seek contributed funds from the institution wherever possible.

Although the motive for this "informal" cost sharing requirement is easy to understand, the practice is nonetheless injurious to the research enterprise. It must be understood that the funds supplied by universities for this purpose are not new money; they instead have been diverted from the support of other research programs. The total amount of research performed will not be increased; it will only be channeled

in particular ways. Any such externally imposed constraint on a university's ability to direct its own research spending leads to a less than optimal use of that institution's resources. Although limited, these resources can be enormously useful to provide insurance so that projects may not lose momentum and staff when extramural awards are delayed. They can also provide needed funds to start new investigators with facilities, equipment and support staff until they are able to compete successfully for outside support. In this way a pool of talent for addressing scientific problems of national interest can be maintained and increased. In such ways the program of the agency may be advanced more than it would be by simply adding the same amount of money on top of an existing grant or contract. It is not just a matter of equity - it is also a matter of efficiency.

There are other ways in which this practice is also undesirable from the standpoint of the agency. Inevitably, the infusion of other funds leads to a dilution of the agency's right to set the goals of the research. More directly, the degree of cost sharing promised by an institution can become a criterion determining which of several competing proposals is funded. This may be neither appropriate nor productive of the best research. On many occasions institutions may find it appropriate to share in the costs of a project funded primarily by one or another federal agency. There is no problem when this is the result of an analysis and determination by the institution that this is the best way to use its resources. It is objectionable when this support occurs not because the project has won institutional support based on its own merits, but rather because of a need to somehow match federal expenditures on that individual project. Many institutions have programs for competitive research grants of university funds. A project is not, and should not be ineligible simply because it is receiving federal support. On the other hand, it should not receive enhanced priority solely because it receives such support. Such forced cost sharing can be very destructive of the cooperation which is essential between federal agencies and universities if we are to maximize research productivity.

Statutory cost sharing has become unduly burdensome. A large administrative network has grown up over the nineteen years that statutory cost sharing has been in effect. The network is necessary to document rather precisely the apportionment of such costs to research and instruction so as to satisfy government auditors. This artificial distinction of costs discourages universities from making voluntary contributions.

GRADUATE STUDENT SUPPORT

The second issue which I wish to address is that of the support of graduate students working in areas of interest to the various mission agencies. This committee has already heard testimony regarding some potentially critical problems in the supply of scientists and engineers in the next ten years. Any shortage in the available pool of technical and scientific personnel will inevitably interfere with the ability of the nation to carry out critical research in the areas of energy, agriculture, defense and space. I am pleased that the various mission agencies have recognized the importance of supporting the development and training of scientists in these areas. Several agencies have initiated fellowship programs to help assure the nation of an adequate supply of trained scientists and engineers in particularly critical areas.

A far larger source of graduate student support comes in the form of research assistantships on projects funded by federal grants and contracts. Graduate training demands research experience. Without exposure to modern techniques, instrumentation, and problems, that training is sterile. Correspondingly, research programs need not only the hands, but also the fresh approach and ideas which students can provide. It is reassuring that this relationship seems to be accepted now by the granting agencies. There is to my knowledge little disagreement at this time between universities and federal agencies regarding the propriety of using grant and contract funds to provide this student support when the students are actually working on the projects. I merely wish to emphasize the importance of continuing this support.

It is in the best interests of both the federal government and universities, indeed of science and technology as a whole.

FUNDING MECHANISMS AND INSTRUMENTS

One question raised in the statement of purpose for this hearing relates to the effectiveness of different funding mechanisms and instruments. I would like to comment briefly on these mechanisms from my own perspective, although I have drawn heavily for background on the report of the National Commission on Research. Funding mechanisms range from individual research projects, large multi-investigatory research programs, research centers, large R&D contracts, which may involve large facilities, on through formula grants to the funding of large national laboratories. Each of these mechanisms plays an important role in the funding of university research, and each may be most appropriate, depending upon the field, nature of facilities needed, and type of problem addressed. The mix of these various mechanisms may differ widely from agency to agency. For example, the Department of Agriculture, unlike the other mission agencies, funds primarily through formula grants.

Nevertheless, each of the mission agencies considered here devotes some fraction of its funds to a competitive small research project program. The maintenance of such programs seems particularly appropriate since it provides an opportunity for the innovative approaches and thrusts in new directions which frequently comprise the cutting edge of science. In many cases, however, the scale of the experiments or the facilities needed demand the cooperative efforts of a number of scientists and engineers, and large research programs and national facilities and national laboratories are obviously required. A prime example of this is the situation in experimental high energy physics. Other examples involve experimental work in fusion, and in many parts of space science. Small seed programs provide the "initiative," while large facility grants provide "stability, continuity and flexibility" which researchers need. This was recognized and formulated as two of the several recommendations of the National Commission on Research. I would

not assert that in and of itself a particular funding mechanism is more efficient than another. I do maintain, however, that in certain circumstances a particular mechanism, may be more reasonable, and therefore, more efficient, than another.

The major types of funding instruments are grants, contracts, and cooperative agreements. Cooperative agreements are appropriate when there is a mutuality of goals and control of the research program between the institution and the funding agency. It is not appropriate to use this mechanism to enforce a cost sharing not dictated by the nature of the relationship, as I have discussed previously. In general, the grant type of funding delegates more authority to the principal investigator and the institution for the management of the project than does a contract. Correspondingly, the agency role is simplified. Universities believe that the grant, an instrument to provide investment in research, is well suited for basic research. The National Commission on Research also recommended assistance as the preferred government funding mode for research. It is particularly gratifying that the Department of Energy has recently adopted grants as a funding instrument for a number of its programs. Clearly, there will always be research efforts which require the degree of management implicit in a contract. Just as clearly, there will continue to be areas of honest disagreement among principal investigators, institutions, and agencies as to whether the degree of control implied by a contract is appropriate. A reasonable assessment would seem to be that there is increased understanding and concurrence among the parties on this issue. Since the National Commission on Research called upon agencies to be willing to experiment with new concepts as the university-government relationship evolves, there have been positive responses. This is encouraging. My colleague Mr. George Dummer will describe some of these developments in greater detail.

Mr. Dummer — Because COGR focuses on the administrative and contractual aspects of federally sponsored programs in the nation's colleges and universities, and because I chair its committee dealing with grant and contract policy, my testimony will be directed, first, at some issues

relating to mechanisms and instruments for funding university research, and secondly, at the methods by which restrictions, whether through security classification or export limitations, are placed on university research projects.

UNIVERSITY RESEARCH CAN BE ENHANCED BY APPROPRIATE REGULATION

Federal support of university research is most effective where it recognizes differences between different classes of grantees and contractors. Identical grant conditions for municipal sewer projects and university research may not serve the purposes of either, and procurement contracts intended for commercial vendors supplying hardware and spare parts for defense systems are not the best funding instruments for procuring university research or encouraging innovation by small business.

Failure to recognize these differences is to a degree more pronounced in procurement contracts and since procurement contracts are most often used by the mission agencies, it is there that the problem can be most acute.

In the final analysis, the mission agencies which have been most effective in funding university research have been those which have recognized that the same policies and regulations cannot be applied uniformly to different types of research performers and have adapted their own requirements to the peculiar needs and attributes of different classes of performers - universities, nonprofits, and small businesses among them.

In some cases, the ability of a mission agency to do this may be enhanced or inhibited by the manner in which statutory authorities or mandates have been drafted.

Let me cite several examples.

The Competition in Contracting Act

There is no question in my mind that P.L. 98-369, "The Competition in Contracting Act of 1984," had, early in the drafting process, the potential for some bizarre results when applied to university contracting. Regulations designed to ensure the competitive acquisition and reprocurement of hardware, spare parts and supplies are not easily applied to university research involving unique and innovative proposals which spring from the minds of academic scientists and engineers and their research groups. Scientific and engineering concepts at the state of the art are not as interchangeable as wrenches, ash trays, and toilet seats.

During the drafting process, however, several provisions were added which recognized the different attributes of contractors performing basic research. One in particular, recognized that the process by which basic research proposals are submitted in response to announcements of a Federal agency's research interests, are subjected to rigorous peer or scientific review, and awarded to only a small percentage of those applying, was in itself a form of competition. Without the statutory provision and prompt agency implementation, CICA could have had a disastrous impact on the procurement of basic research by those mission agencies which most significantly support it.

Government Rights in Data Policy

The regulations proposed by the mission agencies with respect to federal rights in data and copyrights are an example of where the failure to differentiate contracts for university research from contracts for the procurement, or reprocurement of hardware, spare parts and supplies, could have serious adverse consequences for the university community.

If the regulations are implemented as proposed they would, in effect:

A. Provide the government with rights in data far in excess of those mandated by law or required to fulfill the government's needs and in a manner which is incompatible with the conduct of research and impossible to implement in a university environment.

B. Constitute a new threat to the unrestricted flow of scientific communications by giving federal contracting officers broad discretion to restrict the use, release and distribution of such data by the university which generates it.

C. Treat the right to copyright research results as a right to be granted at the discretion of the federal agency and not as the prerogative of the authors or the universities.

D. Inhibit the use of third party technical data and computer software on federally funded research by subjecting it to excessive federal rights which compromise the commercial vendor's legal protection.

E. Establish a strong presumption of federal agency control over the transfer of technology not involving patents, a presumption which is incompatible with that adopted for patentable subject matter under P.L. 96-517 and undermines effective transfer of technology by the universities which generate it.

Lets examine more closely the question of technology transfer referred to under E. above.

There has, I think, been a general recognition that this country must devote substantial attention to the manner of achieving technology transfer between the research community and the industrial and commercial sector if it is to remain technologically competitive in world markets. Congress has enacted legislation to achieve this in various areas.

One example is P.L. 96-517, the patent legislation which provided that small businesses and nonprofit organizations, including univer-

sities, could retain ownership of patents on inventions resulting from federally funded research, subject to certain licensing and march-in rights designed to protect the public interest. This legislation reflected a preference for technology transfer by the institution that generated it rather than by the sponsoring federal agency and replaced 26 different preexisting federal agency policies on patent rights. It has, in my view, had a significant impact on facilitating increased interaction between research universities and industrial companies, in many cases improving technology transfer even where no patentable inventions in fact result.

One would assume that any federal policy on rights in data would reinforce the legislative policy adopted for patents. Rights in data, which includes technical data and software, cannot be separated from patent right in many cases. As we move toward an information society, we find that technological advances begin to blur the copyright/patent interface. For example, an integrated circuit may involve a copyrightable pattern-generating software program, a chip design copyright under the new Chip Protection Act, and a patent on the novel functions performed by the integrated circuit, and very possibly a trademark.

Consequently, those involved in technology transfer view patents, copyrights, and other forms of intellectual property as intertwined and believe that rights must flow in the same direction as patent rights.

This is in fact the case for small business contractors under the Small Business Innovation Research Act, P.L. 97-219, inasmuch as they retain ownership in technical data and software in the same manner as they retain ownership in patents under P.L. 96-517.

Under the proposed government data regulations, however, the universities do not retain ownership of technical data and software in the same manner as they retain ownership of patents under P.L. 96-517. Instead universities are subject to the same provisions as commercial vendors of hardware and spare parts.

The solution appears simple. The federal mission agencies could simply apply to universities the same rights in data regulations and contract provisions they now apply to the Small Business Innovation Research Program, therefore, making it possible to transfer technology in a coherent integrated manner.

ADMINISTRATIVE SIMPLIFICATION VS. BUREAUCRATIC ACCRETION

In discussing the appropriate climate for university research, we noted that the mission agencies which have been most effective in funding university research have been those which have adapted their own policies and regulations in a manner which recognizes the separate identities and attributes of different classes of performers, including universities.

Closely related is the manner in which the mission agencies develop grant and contract instruments which recognize the realities of how university research is performed and minimize the phenomena which the Government-University-Industry Roundtable of the National Academy of Sciences has characterized as "bureaucratic accretion." This characterizes the natural tendency of some individual or agencies to address and isolate abuse, or anticipate potential abuse, by drafting new regulations and requirements for inclusion in grants or contracts. This is particularly true in those agencies which tend to confuse accountability with accounting.

There are many aspects of grant and contract administration which are vulnerable to either bureaucratic accretion on the one hand, or to sensible simplification on the other.

For example, fixed start and stop dates compartmentalize research into arbitrary time increments, resulting in time consuming and superfluous administration and accounting adjustments. The procurement model, in particular, assumes that research projects have sharp starting and stopping points. This can be addressed by authorizing universities to allow pre-award costs and to extend completion dates of awards and to

carry-forward underexpended funds or unfunded obligations from one discrete accounting period to another.

Controls imposed by federal agencies with respect to inventory and management of property can be burdensome and unproductive, and can be reduced or eliminated in conjunction with more realistic policies with respect to vesting of title in the institution.

Frequently, the requirements for obtaining approval of various administrative actions, such as budget deviations, travel and the purchase of equipment, services and supplies, create unnecessary delay and effort by involving federal agency personnel, whereas under appropriate criteria these can be delegated to the contractor itself.

Other administrative burdens relate to reporting requirements for scientific progress and results, subcontracting and patent disclosures and filings. Similarly, requirements relating to cost sharing, budget deviations and transfer of costs between projects can generate unnecessary effort.

There are, on the other hand, some agencies, or individual activities within the agencies, which are attempting to reverse the tide of bureaucratic accretion and develop simpler but more effective instruments without sacrificing scientific accountability.

Let me cite several examples of those mission agency activities which are currently taking the lead in attempting to tailor the administration of grant and contract instruments to the needs of research.

DOE - Special Research Grant and Contracts

The Energy Research Advisory Board (ERAB) identified burdensome and inconsistent research procurement procedures in a report to DOE in 1983. The specific recommendations of the Board addressed how to reduce the blurring and diffusion of DOE-university administrative contacts due to the multiplicity of field offices, operations offices, and procurement

offices administering university research contracts; greater use of multi-year awards to ensure stability and continuity in university funding; simplifying and conforming the reporting and administrative requirements on university research projects to the experiences and practices of other federal agencies, and improved communications between senior DOE procurement and program staff and representatives of university research administration in order to exchange views on simplifying DOE's university contract and grant policies and procedures.

The panel noted in its discussion the effectiveness of what it called a unique contract instrument now called the Special Research Contract (SRC), which is a streamlined agreement, in some respects much like a grant. It is characterized as a relatively simple document which calls for minimum reporting, provides for advance funding when needed, and is easily renewed, and in the opinion of some university respondents is even easier to administer than grants for similar projects. DOE has not been able to implement all the recommendations of the ERAB panel; nonetheless, it should be noted that DOE has devoted substantial effort to establishing funding mechanisms and instruments supportive of university participation and in improving communications with university representatives.

Last April, for example, the DOE Office of Energy Research (OER), in order to facilitate the use of grants, established the Special Research Grant. The Special Research Grant was developed with help from and was well received by the university community. It has many of the desirable features of the Special Research Contract in dealing with pre-award costs, budget flexibility, carry-forward of unfunded obligations and unobligated funds.

DOD Short Form Research Contract

With the full cooperation of COGR, the research offices within DOD have developed a Short Form Research Contract which simplifies the process of contracting with universities and other nonprofit organizations for research.

This simplified contract eliminates much of the paperwork usually associated with contracts, and makes negotiating with DOD for a research contract reasonably simple.

Extension of Research Management Initiatives to Mission Agencies

One of the recommendations made by the Energy Research Advisory Board with respect to DOE procurement was to simplify and conform the reporting and administrative requirements on university research projects to the experiences and practices of other federal agencies, including DOD, NASA and NSF.

In this connection, it would appear that DOE and other mission agencies are in fact examining more closely the experience and practice of other agencies including those of the National Institutes of Health and the National Science Foundation, which have in recent years taken a number of initiatives in improving research management.

In May of this year, the Research Roundtable of the National Academy of Sciences listed a number of these in a compilation entitled "Current Agency Initiatives for Improving the Sponsored Research System." They included the following:

NIH - The Javits Neuroscience Investigator Award, a seven-year R01 award given to distinguished investigators with a record of substantial contributions who can be expected to be highly productive for the next seven years.

NIH - The NCI Outstanding Investigator Grant, awarded for a maximum period of seven years but renewable, for the purpose of providing long term support to experienced investigators with outstanding records of research productivity.

NIH - Program Project Grants, awarded to an institution on behalf of a principal investigator for the support of a broadly based, often multi-disciplinary, long term research program with a

particular major objective or theme; and Center Grants, awarded to an institution on behalf of a program director and a group of collaborating investigators, for the support of long term, multidisciplinary programs for research and development.

NIH - The PHS initiative to reduce the administrative burden on grant recipients, including expansion of the authorities delegated to grantees under the Institutional Prior Approval System (IPAS).

ONR - The Total Business System Review (TBSR) which emphasizes review of a university's various business management systems rather than individual contract-by-contract or grant-by-grant transactions.

NSF - Accomplishment-Based Renewal Proposals, which is an alternative mode for submission of renewal proposals under NSF research grants, the intent of which is to decrease paperwork and reduce administrative burdens to the research community.

NSF - Two-Year Extensions for Special Creativity, an experimental mechanism permitting extension beyond the initial grant period in order to offer the most creative scientists increased opportunity to attach adventurous "high risk" research questions in the same general scientific area but not necessarily directly related to those pursued under any existing research grant.

NSF - Fixed Amount Awards, used for certain categories of grants, and intended to help reduce some of the administrative burden and record keeping requirements for both grantees and the awarding agency without a loss in appropriate accountability.

NSF - Presidential Young Investigator Awards, providing cooperative research support for promising young science and engineering faculty.

NSF - Organizational Prior Approval System, which was made available to eligible grantees after a three year experiment conducted jointly with the Association of American Universities (AAU). The experiment dealt with ways to attune the federal grant support system to the needs of grantee management by redefining the grant relationship to (1) delegate most prior approvals to grantees; (2) provide grantees with additional authorities needed to permit effective management; and (3) permit limited aggregating or relating of individual projects.

Universities are now proposing an interagency test, limited in scope and term, to study the effect of delegating a common set of prior approval authorities to universities. The prior approval authorities to be examined have already been delegated to universities by one or more federal agencies, so the test is not to focus on the authorities themselves, but to study the effects and feasibility of extending and standardizing these components of post award management.

University Liaison

Another factor which can have a substantial impact on the effectiveness with which agencies interact with university grantees and contractors is the establishment of offices or activities which have, as a principal responsibility, interaction and liaison with the research community. Such activities include the DOE Energy Research Office of University Affairs and the ONR Office of University Affairs. ONR also has Resident Representatives on site or close to several of the larger research universities. NASA discontinued its office of university affairs several years ago.

IMPACT OF NATIONAL SECURITY CONSIDERATIONS

The implications of national security considerations with respect to the university-government relationship and the broad sweep of scientific communications have become a subject of concern and debate at many levels. For those of us who deal primarily with administrative and legal aspects of university research, the implications of national security are most apparent in the way federal agencies deal with classification and with unclassified but critical information in research contracts.

Classification

The current system of security classification was established in 1982 by Executive Order 12356 and a number of commentators characterized it at the time as reversing the trend of prior security classification systems toward openness, and expressed concern that "academic research not born classified may, under this order, die classified."

Concern has also been expressed that the new order gives greater authority to government officials to intrude upon academic research by imposing classification at any stage of a research project. Thus the Order could inhibit academic researchers from making long term intellectual investments in non-classified projects with features that make them likely subjects for classification at a later date.

I am not aware to date of any significant trend toward the classification of on-going research as a result of the Executive Order. Most universities will not undertake classified research on-campus, except perhaps in separate research centers or institutes, and will disengage from research that becomes classified. For this reason I suspect that federal agencies are as reluctant to award potentially classified research to universities as universities are to accept it.

However, university concerns over the mid-stream classification of on-going research projects appears to have been rekindled by statements

made by government officials with respect to the Strategic Defense Initiative. Faculty members have expressed concern that projects may be classified after it is too late to withdraw without severe disruption to the research, or that, as work becomes increasingly sensitive, it will be turned over to private contractors. Thus, there is again the fear of making long term intellectual commitments to projects that may subsequently be classified.

Export Controls

Until roughly 1980, I suspect that many of us would have thought of classification as the principal method by which the federal government controlled the dissemination of scientific research results for purposes of national security. In 1980, however, a DOD sponsored research program involving Very High Speed Integrated Circuits was made subject to export controls and two universities participating in the program were asked to accept restrictions on the publication of the results and the employment of foreign nationals on the research.

At that point university research administrators, many for the first time, became aware of two sets of export control regulations: the International Traffic in Arms Regulation, or ITAR issued by the Department of State; and the Export Administration Regulation, or EAR issued by the Department of Commerce.

Trying to understand the complexities of the licensing process established by these regulations, and understand what university-generated technical data might be subject to export controls, proved bewildering to many.

As a result, many universities concluded that the imposition of export regulations on university research presented problems no less severe than the imposition of classification, and a number of university presidents publicly urged that where controls were necessary, classification should be used in preference to export controls.

Controls on Militarily Critical Technology

From the standpoint of those actually conducting research and those involved in the administration of university research, the issues requiring attention at the present time relate to restrictions on scientific communications involving critical but unclassified technology, and attempts to arrive at a position acceptable to both the federal agencies and the universities.

The principal focus of this effort is the Militarily Critical Technologies List, or MCTL, maintained by the Department of Defense since 1980.

The technologies covered by the MCTL are so broad in scope and definition that they appear to cut across large segments of university research. Consequently, restrictions on research related to such technologies present problems no less severe than those posed by the export control regulations. A number of universities have again taken the position that such technology should either be classified or publishable without restriction.

A report issued by a Task Force of the Defense Science Board in January 1982 stated the problem as follows:

> "DOD is caught in a dilemma. If it vigorously attempts to regulate the flow of scientific information in the scientific community, it would jeopardize the strength and vitality of the very community it is seeking to revitalize for the sake of national defense. On the other hand, if DOD abandons any attempt at regulation in the university context, it could seriously compromise and, in certain cases, totally undercut other efforts to control the out-flow of militarily critical technology. The middle ground is a difficult one to establish."

In October 1984 DOD adopted a policy which (1) stipulates that classification will be the sole mechanism for control of fundamental research in science and engineering under contracts with colleges and universities, and (2) defines "fundamental research" in terms of the 6.1 and 6.2 appropriation categories with limited exceptions. Any restrictions on research not defined as "fundamental" would be agreed to up front as part of contract negotiations and universities unable to accept such restrictions could decline the contract at the outset.

Mr. SLAUGHTER (acting chairman). Thank you, gentlemen.

In connection with the militarily critical technologies, do you see that we can arrive at a satisfactory working arrangement, or would a great deal of that research have to go into Government laboratories?

Mr. DUMMER. Well, at the present time, the 6.1 and 6.2 categories would cover, for example, most of the research done at my institution on campus.

The 6.3 appropriation, where the controls are likely to be most anticipated, is at my own institution less than a few hundred thousand dollars compared with the millions that come from other sources.

So, the question is how much of the 6.2 category funding would fit within those so-called rare exceptions which have to do with a high likelihood of displaying performance characteristics of military systems or, I think, of manufacturing technology.

At the present time, I would especially hate to speculate how much, but I don't—unless the trend accelerates beyond what I have seen thus far—expect that to be dramatic.

Mr. SLAUGHTER. Yes, Dr. Miller.

Dr. MILLER. Mr. Chairman, I would just point out that in addition to Government laboratories, the not-for-profit institutions such as ours do conduct classified research.

We find it very easy to do. We have special facilities. We worked in some very highly classified areas. We also do proprietary research for businesses. That, in a way, is something that does distinguish us from universities.

I have spent 20 years of my life at Stanford University, so I am very familiar with the university side as vice-president for research and later the professoriate there.

It is very difficult to do classified research or even proprietary research there for very good reasons. But there are other institutions other than the national laboratories where it is done.

Mr. SLAUGHTER. Glad you made that point. Didn't mean to slight the private institutions.

Mr. DUMMER. I might add, Mr. Chairman, of course universities have, under circumstances where it is anticipated and planned and part of their regular program, such as some of the FFRDC's of which the Lincoln Laboratory associated with MIT is one, that performs major classified research.

I think the new software institute, as I recall, Carnegie-Mellon, is going through the process of determining to what extent potential classification may be appropriate there.

I think each institution may decide whether it will or will not be able to respond, whether it is public service or in the interest of national security, whether there is a compelling need by setting up the mechanisms by which to do classified research; but I think they hesitate to do it on the campus proper where the interaction of faculty and students in an open environment is essential.

Mr. SLAUGHTER. Thank you.

Mr. Stallings, do you have any questions?

Mr. STALLINGS. I would like to address a couple of questions to Dr. Levy.

You indicated that over the past couple of decades, the health of university research has become less of a concern and interest to NASA. What do you think accounts for such a change in attitude, and is a reversal of that attitude developing at this time?

Dr. LEVY. What I have said is I have been told by both congressional staffers and people within NASA that the NASA charter mandates the agency to carry out a mission which has as none of its parts the health of university programs, per se.

I would say that within the program offices—and few speak to individuals associated with the agency, particularly those who are charged with running the research programs—they, as individuals, do have some considerable concern over this question.

But the real question comes when moneys are allocated. Is any concern taken over whether or not there will be a large negative or a large positive impact on the university programs? And the answer is no.

I would say that that is a problem, I am afraid, in this part of town as much as it is in the agency when the crunch over real dollars comes in as much as it is in the Office of Management and Budget.

So, I don't think it is a matter of ill will or lack of concern, but in the final event when dollars get sliced off the budget and moved here and there, in all of the parts of this town that are responsible for that process, the university programs do not seem to loom large as major concerns.

Mr. STALLINGS. Also, in your opinion, what is the reason for the failure of the United States to respond to the appearance of the comet, Halley's Comet?

Dr. LEVY. Didn't want to spend the money. There were programs brought forward of a whole various spectrum of opportunities that were brought forward in the later 1970's, and they never made their way up through the agency, through the White House and into the Congress.

I can recall spending an impassioned several minutes on the telephone with the previous Presidential Science Advisor during a budget process, urging that low thrust electric propulsion development continue to be kept in the budget simply to provide the opportunity for the Halley's Comet mission that was being planned, and that simply didn't happen.

I think that it was a manifestation of a turn in national mood and a sense that a loss of national vigor in these areas more than it was anything else.

It is not something that happened in some well-defined office over at the agency. It is something that happened in this town, generally.

Mr. STALLINGS. Thank you.

Mr. SLAUGHTER. Dr. Levy, I think you stated that one of the problems we have in developing young scientists is they don't have very good career opportunities, and so I guess the question—that is equivalent to saying we are not doing enough research in this country generally, scientific research.

Maybe you disagree with that. Maybe I have drawn the wrong conclusion, but if that be true, I would like your comment on that. Is it because the Government is not spending enough? I gather you think so, certainly in the case of space science.

How much of it is attributable to industry not spending enough, and, of course, I know what we have got to do to make Government spend more money is to convince the Congress to set up the right kind of program and so on.

I am glad to have your comments on that, but in particular, if industry is not spending enough, why?

Dr. LEVY. Let me make sort of a general comment. I think that there are several phenomena involved here.

One of the phenomena that is involved is that there has been a market unsteadiness in Government programs, so that there was a time of great vigor 20 years ago in trying to get programs established which expanded university faculties and then followed by a marked turn down which provided bare sufficient research opportunities to keep those who were started 20 years ago working and busy in research programs and providing no opportunities for new scientists following them.

I think part of—there are two issues here. One is that I don't believe that the level of research spending is where it ought to be, and second, the very large swings and fluctuations in the way this Nation supports science have been very damaging in that it filled up all of a sudden all of the positions and career opportunities, and then just as suddenly cut things down by about a factor of two in terms of the real level of expenditure in Federal funds, and then suddenly cut off the opportunity.

So, it is a matter not only of just the level of spending, but it is also this unevenness when we suddenly get excited, and then we lose interest.

I guess I don't feel particularly competent to discuss the question of spending in industry. My major experience and concerns have been with fundamental research programs, and fundamental research is not, in fact, a major component of most of the industrial research activities.

That is a question, I guess I would prefer to defer to somebody else.

Mr. SLAUGHTER. I was going to ask. Other members of the panel may want to comment on this, too.

Dr. Ebel.

Dr. EBEL. Yes. First of all, let me point out, as Dr. Levy just said, you are dealing here in the question of training young scientists with a very long time scale.

You talk about graduate training, which in many scientific areas can approach 7 years past the bachelor's degree. Plus, it has become traditional and necessary frequently to have post-doctoral training of 2, 3, 4 years.

So, you are talking about a time scale of roughly 10 years. One of the problems you have is this problem of fluctuation in that if job opportunities are reduced, then people are discouraged from entering the fields, and so it creates a problem not immediately, but ten years down the road, and this then means that surprisingly, an effect of increased involvement of industries in research can act as

a competition, as an alternative source to the training of basic scientists or to the training of university faculty members.

And so the problem—part of the problem right now which we are seeing in engineering is, of course, job opportunities in engineering are too good.

The problem really is a fluctuation problem here, and my own field 10 years ago, 15 years ago, perhaps, one said that we had enlarged the faculties in the areas of high energy physics so much that there really weren't any more opportunities, and students become discouraged.

Now, we are looking at the fact that median ages are 50, 55 in departments. Ten years down the road, we aren't going to have the faculty available.

So, I think that as Dr. Levy was pointing out, it is not just a question of funding, but it is a question of stability of that funding.

And it is a question also of recognizing that when you are funding, if you want a long-term research program, you have to not only fund the individual research projects, but you have to recognize what the impact of that funding is going to be upon the training of next year's crop or the next decade's crop or next century's crop. That is part of our problem.

Mr. SLAUGHTER. Dr. Miller, do you have any comments on that?

Dr. MILLER. Well, I would really support what has been said, that the steadiness is an important issue.

I suppose sometimes we take the fact that we may have an oversupply of scientists in some areas as evidence that we have been producing too many, but the other side of the coin that you just mentioned is maybe we are not doing enough research that should be occupying them.

In my own testimony, I mentioned I think the process has worked very well by and large, but a more global view of what are important areas to be working in—new areas—is perhaps lacking in our interagency kind of coordination, because we probably are not spending enough in certain areas that are going to be profitable in the future.

Mr. SLAUGHTER. Mr. Dummer, do you have any comment?

Mr. DUMMER. No, Mr. Chairman.

Mr. SLAUGHTER. Well, gentlemen, I want to thank all of you for your testimony today and for your contributions to our task force study.

The task force stands adjourned until October 22 when we will continue this set of hearings on Science in the Mission Agencies and the Government Laboratories.

Thank you all for coming today.

[Whereupon, at 11:50 a.m., the task force adjourned, to reconvene on October 22, 1985, at 9:30 a.m.]

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

TUESDAY, OCTOBER 22, 1985

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
SCIENCE POLICY TASK FORCE,
Washington, DC.

The task force met, pursuant to notice, at 9:37 a.m., in room 2318, Rayburn House Office Building, Hon. Don Fuqua, chairman of the task force, presiding.

Mr. FUQUA. The task force will be in order.

Today's hearing is the fourth in a series of six hearings on science in the mission agencies and Federal laboratories. This hearing will examine science policy in the Federal laboratories and will also consider the implications of the reemergence of the Department of Defense as a major sponsor of university research.

The first of our distinguished witnesses will be Mr. David Packard, chairman and cofounder of Hewlett-Packard. Among his many activities, Mr. Packard is a member of the White House Science Council where he chaired that Council's laboratory review panel, and he is the Chairman of the President's Commission on Defense Management.

I also might note that in his spare time, he helped design quite a bit of the new Monterey Bay Aquarium which is directed by his daughter and was featured in the June issue of *Smithsonian* magazine. Mrs. Fuqua and I had a chance to visit that back in August, and it is everything that it says about it.

So, Mr. Packard, we would be happy to begin with you this morning.

[A biographical sketch of Mr. Packard follows:]

DAVID PACKARD

Born: September 7, 1912, Pueblo, CO.

Married: Lucile (Salter) Packard April 8, 1938.

Education: Stanford University—B.A. 1934, Stanford University—E.E. 1939.

Honorary Degrees: Doctor of Science, Colorado College, 1964; Doctor of Laws, University of California, 1966; Doctor of Laws, Catholic University, 1970; Doctor of Laws, Pepperdine University, 1972; Doctor of Letters, Southern Colorado State College, 1973; Doctor of Engineering, University of Notre Dame, 1974.

Business: Hewlett-Packard Company, 1501 Page Mill Road, Palo Alto, CA.; Cofounder and Partner, 1939–1947; President, 1947–1964; Chairman of the Board and Chief Executive Officer 1964–1969; U.S. Deputy Secretary of Defense, Washington D.C. January 1969–December 1971; Hewlett-Packard Company, Chairman of the Board, January 1972–.

Director: (Current only) The Boeing Co. 1978–, Genentech, Inc. 1981–.

Trustee: Herbert Hoover Foundation, American Enterprise Institute, The Hoover Institution.

Activities: President, Board of Regents, Uniformed Services University of the Health Sciences 1975–1982; The Trilateral Commission 1973–1981; Fellow, Institute of Electrical and Electronics Engineers; Member, National Academy of Engineering; Lifetime Member, Instrument Society of America; Member, the Business Council (Past Chairman, December 1972–December 1974); Member, the Wilson Council; Member, The Business Roundtable; Member, Industries Advisory Committee, The Advertising Council, Inc.; Member, US–USSR Trade & Economic Council Committee on Science & Technology 1975–1982; Member, Board of Overseers, Hoover Institution, Committee on the Present Danger 1975–1981; Founding Vice-Chairman, The California Roundtable; Director, Alliance to Save Energy; Director, Foundation for the Study of Presidential and Congressional Terms; Vice Chairman, Santa Clara County Manufacturers Group; Vice Chairman, The Atlantic Council 1972–1983; Member, White House Science Council; Director, Wolf Trap Foundation (Vienna, Va.); Co-founder and past chairman, American Electronics Association; Vice Chairman, California Nature Conservancy 1983–; Chairman, U.S.-Japan Advisory Commission 1983–; Director, National Fish and Wildlife Foundation 1985–; Member Commission on Executive, Legislative & Judicial Salaries 1985; Chairman, President's Commission on Defense Management 1985.

Clubs: San Francisco: Bohemian, Commonwealth, Engineers Club, Pacific Union, World Trade; Los Angeles: California Club; Washington, D.C.: Alfalfa Club, Capitol Hill; New York: The Links.

Awards: American Electronics Association Medal of Achievement "For Significant Contributions to the Advancement of Electronics" (1960); Herbert Hoover Medal, the highest honor awarded by the Stanford Alumni Association (June 1966); Peninsula Manufacturers Association "Man of the Year for 1968" (Feb. 1969); Gantt Medal, presented by American Management Association (Feb. 1970); Crozier Gold Medal, presented by American Ordnance Association (and life membership in the Association) (April 1970); "Distinguished Alumnus of the Year", named by Alpha Delta Phi at Stanford University (May 1970); Distinguished Citizen Award, presented by the Palo Alto (Calif.) Chamber of Commerce (Feb. 1972); James Forrestal Memorial Award, presented by the National Security Industrial Association (March 1972); Award for Very Distinguished Public Service, presented by the Federal City Club of Washington, D.C. (March 1973); Business Statesman of the Year Award, presented by the Harvard Business School of New York (April 1972); The Silver Quill Award, from the American Business Press, Inc. (April 1972); Grand Cross of Merit, presented by the Federal Republic of Germany (July 1972); Benjamin Fairless Memorial Medal, presented by the American Iron and Steel Institute (May 1972); Founders Medal (presented jointly to Messrs. Packard and Hewlett), awarded by the Institute of Electrical and Electronics Engineers (March 1973); Business Statesman of the Year, presented by the Harvard Business School Club of Northern California (May 1973); Industrialist of the Year (in conjunction with William R. Hewlett), presented by the California Museum of Science and Industry and its affiliate, the California Museum Foundation (May 1973); Silver Helmet Defense Award, presented by AMVETS (August 1973); Medal of Honor, presented by Electronic Industries Association (March 1974); and The Washington Award, presented by the Western Society of Engineers (Feb. 1975).

Also: The American Society of Mechanical Engineers and the Institute of Electrical and Electronics Engineers (April 1975); SAMA (Scientific Apparatus Makers Assn.) Award, presented jointly to David Packard and William R. Hewlett (May 1975); Gold Medal Award, presented by the National Football Foundation and Hall of Fame (Dec. 1975); Good Scout Award, presented by Stanford Area Council, Boy Scouts of America, Palo Alto (Dec. 1975); Vermilye Medal, presented jointly to William R. Hewlett and David Packard by The Franklin Institute, Philadelphia (May 1976); Award for International Achievement, presented by The World Trade Club of San Francisco (May 1976); Award of Merit, presented by the American Consulting Engineers Council Fellows (Oct. 1977); Achievement in Life Award, presented by the Encyclopedia Britannica (Nov. 1977); Founders Award, National Academy of Engineering (Fall 1979); 1980 Engineering Award of Distinction, presented by San Jose State University (June 1980); Thomas D. White National Defense Award, presented by United States Air Force Academy (May 1981); Distinguished Information Sciences Award, presented by Data Processing Management Association (Oct. 1981); "1981 Citizen of the Year," Police Activities League, San Jose, Ca.; John Fritz Medal, presented by the Founders Society, WESCON (Sept. 1982); Sylvanus Thayer Award, United States Military Academy, West Point, New York (Oct. 1982); and Environmental Leadership Award, Natural Resources Defense Council (May 1983).

STATEMENT OF DAVID PACKARD, CHAIRMAN OF THE BOARD, HEWLETT-PACKARD COMPANY, PALO ALTO, CA

Mr. PACKARD. Thank you very much, Mr. Chairman, and members of the committee. I am pleased to have the opportunity to speak to you on a subject that has been of considerable interest to me over a long period of time.

As I think you know, we had a subcommittee of the White House Science Council that spent about a year looking at the Federal laboratories. We made some recommendations, and I assume that your committee has seen a copy of those recommendations.

In thinking about this, I recall that I first called on the Naval Research Laboratory in 1940, so I have been involved in these laboratories for quite a long period of time. Actually, our company has had a very good relationship with a number of the Federal laboratories because we have been in the scientific instrument business and we have worked very closely with these laboratories over the years.

Now, this morning, I am going to concentrate on a few rather simple but I think rather fundamental recommendations that I believe would result in an improvement in the return we get for the money the Federal Government is spending in supporting research and development, not only in the laboratories but also in the agencies. I am going to begin with some rather simple statements, but I think it is very important to keep in mind what the basic fundamentals of this situation are. I think if we do that, it may be helpful.

I would like to begin by recalling that progress in science comes from two basic endeavors. The first one is people who think, and the second is people who carefully design and conduct experiments. There are two very simple guidelines which, it seems to me, if they are understood and taken into consideration, could make an immense improvement in the way the Federal Government supports science.

First, again, the scientists are people who think. They should be selected and supported on the basis of the quality of their scientific work, not simply on how well they can write a proposal asking for support. When they are supported, they should not be burdened with preparing unnecessary progress reports, effort reporting, and other unnecessary work which simply takes away their time in which they are to do their real work.

The second proposition is that the scientists must have the proper equipment in order to carefully design and conduct experiments. The equipment needed to keep scientific work at the forefront of technology today is much more complex and much more expensive than it was in the past. Modern equipment is more accurate and often includes computational capability which makes it much more efficient, and it is a very serious handicap for a scientist to have inadequate equipment and inadequate facilities for the work to be done. So, it seems to me that when the Federal Government provides financial support for a scientist, the Government should also take into consideration the need for financial support for equipment and the facilities that are necessary to do the work.

I think if this is done, we will all get a better return for the work being supported.

These observations apply to people doing development work as well as basic science. Experimental work for development would include testing to prove the integrity of the proposed design. There would also be drawings and instructions to produce models and so forth. So, these observations, I think, are fairly general and I think if they are kept in mind as various issues are considered by the Congress, they could be quite helpful.

I want to make a few more specific comments about how the agencies might do a better job in selecting the scientists they want to support.

I believe the peer review process is useful, but I don't think it should be carried too far. I have already mentioned that the selection of the people to support should be based on their performance to the fullest extent, and this implies that the peer review process should probably focus more on what the scientist has actually done and not just on what he says he can do.

I have seen many excellent proposals prepared by people who sound very credible but who have had, in fact, a very dismal record in what they could actually do.

In our report on the Federal laboratories, we recommended that each laboratory have a review committee and that the review committee should report not just to the laboratory director but to the agency or organization responsible for the laboratory. The review committee would be, in a sense, another kind of peer review. Quite often what happens is the laboratory committee develops a fairly close rapport with the laboratory director and is not often as objective as it might be in making recommendations. We think that using a review committee to evaluate the performance of a laboratory should serve to reduce the number of routine reports that are now required. In basic terms, an objective review of the work done by the laboratory would be much more useful than the myriad of reports, progress reports, and other things that are now required.

There is another issue here, and that has to do with the fact that good research work cannot always be done in discrete quantums. There should be some continuity, some long-term stability to these programs, and this is done to some extent. Specifically, a Federal laboratory or a college or university that has demonstrated good work should be supported over a longer period of time. I think that this emphasis on longer term support of research activities that have demonstrated good performance would be a very important contribution that would improve the efficiency with which these funds are used.

This, of course, should involve a period review of the performance by a review committee. I think, in many ways, it would be better to reduce the peer review process to the beginning of a new program. I think if you are going to do something, it wouldn't hurt to make a mistake once in a while and have a little more flexibility in who you support. Sometimes, the laboratory director knows about a young scientist in his organization, and his recommendation could be entirely appropriate for a program. These should be reviewed as you go along.

It has often been thought by people who have been involved in the process that the review procedure tends to reduce innovation in that somebody comes up with a new idea completely out of his traditional field and the peer review committee doesn't always understand it, and sometimes you are not able to get things done that could be very productive otherwise.

There is another very specific matter that I think this committee could be helpful with, and it has to do with research at colleges and universities and particularly in that area that is generally known as basic research. Federal agencies and Federal laboratories find it difficult to place research contracts at universities because of the many detailed requirements that are placed on that contracting procedure. I think it would be very helpful if all the Federal agencies and the Federal laboratories could be given specific authority to give contracts to colleges and universities on a sole-source basis. There is, in fact, in my opinion, absolutely no place for competitive bidding for research placed through colleges and universities, and I think this committee could make an immense contribution to American science by obtaining the support of the Congress to exempt research contracts placed with colleges and universities from competitive bidding requirements and also from many of the other requirements such as small business, equal opportunity, and so forth. These requirements take time and add cost and I think, in fact, they don't often help very much with the social reform that is intended.

I suppose, also, it is too much to ask the Congress to refrain from logrolling activities where research at colleges and universities is involved, but it seems to me that here again it would be a contribution if this work could be supported strictly on the basis of its contribution to the quality of American science.

Universities, as I think you know, are having difficulties with the equipment and facilities available for the research people. It varies a great deal, of course, from university to university. Some of the major research universities are getting good support from the private sector, from business, and doing relatively well but, in general, there is a real problem with the equipment and facilities. The Federal Government has done a very fine job in the area of high energy physics where facilities costing hundreds of millions of dollars have been provided, and, of course, this work couldn't be done without this support for these facilities. In my opinion, there are many other areas of science which might make an even more important contribution to our economic well-being, the health of our citizens, and to the quality of life than high energy physics. I think a few tens of millions of dollars for equipment and facilities would bring a big return in the productivity of scientific work in these other areas.

At this point, I want to make a few comments about the tax credit for equipment given to colleges and universities by private sector business organizations. This arrangement, I think, is generally good and I support it, but there are a few problems with it, and I want to point these problems out to you, not with the idea that I am against this tax credit but that there are some additional things that should be considered.

This arrangement does have the advantage that most corporations have an idea about the quality of work being done at various universities, and they tend to give equipment where quality work is being done, where good students are being educated, so this is a very positive feature of the problem. Some corporations, in addition to giving equipment, provide funds for installation, and operation and maintenance. Not all of them do so, and it is very important, I think, that they do so.

Sometimes, equipment is given to colleges and universities, and they don't have the money to install it and keep it in operation. Perhaps this investment credit should be expanded to allow some financial support for installation and maintenance and operation of equipment which is being given to the colleges and universities.

Corporate contributions don't completely solve the problem, however, and I think it is fair to say that some corporations look on this to some extent as an advertising or sales gimmick. I might suggest that probably colleges and universities around the country have received a good many more personal computers than they really need and not enough of other kinds of equipment. So, this is an area—I don't know how to correct it, but this tends to be the situation.

Another problem with this Tax Credit Program is that it does not extend to all colleges and universities on the basis of their real need. I think, therefore, that the Tax Credit Program should be supplemented by direct grants by the Federal agencies, and I think that the Federal agencies and laboratories will receive more for their money if they take the responsibility for making sure that the equipment is available for the people they support.

The Department of Energy has a special problem that I want to mention here. We came upon this in our Federal laboratory study. It is simply that the Department of Energy tends to treat research grants like contracts to do construction rather than contracts to do research. They have field offices that look over the work being done. They often require monthly reports, and I have seen a number of cases where a monthly report by a scientist or an engineer doing research work is just a complete waste of time. I have known a few cases where the person being supported has asked to be relieved of these monthly reports, and the agency has granted that relief. However, this, in fact, requires paperwork by the ton. It is absolutely unnecessary in most cases, and it poses a large burden on the people who are doing research work, and simply takes time from the work they should be doing.

This problem came about, I think, because the Atomic Energy Commission was organized to be able to manage a large number of facility construction programs. Here it was desirable to have field offices and require progress reports and so forth. This apparatus was transferred to the Department of Energy, and it should be phased out. If this could be done, I think it would save many millions of dollars a year and provide a much better environment for the scientists involved to have more time to do the scientific work instead of paperwork.

I want to say a word about Government-owned laboratories like NRL, NBS, and so forth. I am pleased to note, Mr. Chairman, you

have introduced some legislation to help in the administration of these federally operated laboratories and other areas.

I want to emphasize that because these laboratories and other activities are under civil service regulations, they have not been able to hire, motivate, or retain the best scientific people, the scientists, and engineers. They can't get the best young people coming out of the schools and universities, and senior people have a good many attractive offers from outside the Government, so the quality of the personnel is often not what it really should be.

This program could be patterned after one that was in place at the Naval Ordnance Laboratory at China Lake. I visited that laboratory and found that the director was able to do a much better job in keeping, attracting, and motivating his people. This is something I would recommend very strongly that you consider and put into place if you can.

I don't have any real objection to making this program all inclusive. The Defense Department does have some difficulty in attracting and keeping good people, and if it could be done on a broader basis in the Federal laboratories, that would be I think a very good step. But I hope if the full program isn't feasible that you will at least work hard to get this step for the laboratories as a first step in the right direction.

One choice, of course, would be to place the federally owned laboratories that are federally operated under a contractor operation. I don't think it would be wise to do so. I think the present mix between company operated and federally operated laboratories is about right. Some of these laboratories like the National Bureau of Standards, for example, have a long tradition of good contribution to science and technology, and I think it is a good balance to keep some federally operated laboratories. So I would not recommend that these all be transferred over to outside management.

There is another matter that we raised in our Federal laboratory panel, and it is a very important idea in connection with the administration of research work. That is that research people should be allowed to spend at least a part of their time on some ideas of their own choosing. This proposition, I think, is supported by almost everyone who has had much experience in Federal laboratories.

It is simply that if a scientist or engineer is working on a particular project, quite often there are some ideas that occur to him that would be unrelated to that particular project, and sometimes this can be a very important source of innovative ideas. We recommended that at least 5 percent and some members thought it should be 10 percent of a research person's time should be allowed as free time for him to work in areas of his own choosing. I think this is an idea that also should be evaluated from time to time, and it certainly is not going to be productive to allow people to spend 5 or 10 percent of their free time without accomplishing something. We felt that these allowances should be reviewed and those people who in fact come up with some useful ideas over a period of time be given a little more flexibility. So, it should be evaluated on the basis of the results that are actually achieved.

On that point, I want to make a comment about independent research and development for defense programs. I know that your

committee is not involved in the defense-supported activities, but because independent research and development has a possibility of making a larger contribution to areas outside of those related to defense, I wanted to make a comment about this.

The independent research and development for defense programs was originally based on the understanding of the importance of giving scientists and engineers some free time from their assigned work to explore their innovative ideas, the very thing I have been talking about. In about 1970, the Mansfield amendment was enacted by the Congress which required independent research and development to be limited to ideas related to military work. This required that such IR&D as was undertaken had to be justified and documented to demonstrate this work had a military potential.

While this requirement has been repealed, the practice has not improved very much. I think that there are a great many potential commercial fallouts that could be obtained from military research and development if this independent research and development proposition were put back into place on the original basis. I think the areas that your committee is involved in would benefit because, after all, we spend a very large amount of money in research and development in the Defense Department, and I think, to the extent we could get support from the Congress to encourage the Defense Department to change their practices here, it would be very much to the benefit of our country.

These are just a few ideas. There is one other matter I wanted to comment on. I did not include it in my paper.

We are doing at the White House Science Council another study on the relationship of the Federal Government with our universities. This is directed largely to the support of research. We have looked at the two ways in which the Federal Government supports research and development and the way they handle their overhead. One of them is used by the NIH, and the other one is typical of the National Science Council and other agencies.

It seems to us that it is an unnecessary burden to have two completely separate systems in the country here of dealing with this matter of overhead on research programs. I can't give you any strong justification for one system or the other. There are proponents of both, but it seems to me to require universities and other people to deal with two different ways of handling this thing simply adds to the real cost of overhead, and anything we can do to minimize the overhead and put more of the money we are providing into the work of the scientists and the engineers, the research people, I think would have a very productive fallout.

There are many other issues involved here, but I thought I would limit my presentation today to these matters which I think are all fairly straightforward, and I think if these were given some consideration it would in fact improve the return the Federal Government gets for the amount of money it is spending.

I appreciate the opportunity, Mr. Chairman. I would be glad to answer questions.

[The prepared statement of Mr. Packard follows:]

STATEMENT OF

DAVID PACKARD, CHAIRMAN OF THE BOARD

HEWLETT-PACKARD COMPANY, PALO ALTO, CALIFORNIA

BEFORE THE

SCIENCE POLICY TASK FORCE

COMMITTEE ON SCIENCE AND TECHNOLOGY

U.S. HOUSE OF REPRESENTATIVES

OCTOBER 22, 1985

Mr. Chairman and Members of the Committee on Science and Technology, I am very pleased to have this opportunity to appear before you to discuss the subject of science in the mission agencies and the government laboratories. This, as I think you know, is a subject that is of considerable interest to me. I was involved several years ago in a study of the Federal laboratories done by a sub-committee of the White House Science Council. In addition to that, I have had a great deal of experience over the years one way or another with the Federal laboratories. It was about forty-five years ago when our company was first getting started, we had probably twenty or thirty employees at that time, when I called on the Naval Research Laboratory here in Washington. We worked closely with NRL for many years. Since that early beginning our company has been involved many times with government laboratories and I have also had a good deal of involvement, one way or the other, in the mission agencies and including, of course, the Department of Defense.

The Federal government has provided an enormous amount of support for American science during the last four decades. It is in a large part because of this massive Federal support that the United States has taken a leadership role in science over the rest of the world. The leadership of American science has contributed a significant increment of superiority to the armed services of our country. It has enabled us to put a man on the moon and bring him back safely. It has been responsible for brilliant achievements in medical science. American science has made an invaluable contribution to the strength of our economy, our productivity and our competitive advantage in many sectors of the economy.

I am sure your Committee knows all of these things so I will not undertake to document these observations with the facts and figures which I am sure you already have.

Although the Federal support for American science has been very large in magnitude, it has not been as effective as it should have been. I believe there are a number of specific things that could be done to improve the way the Federal government supports American science, in the agencies, in the Federal laboratories and in the colleges and universities of our country. I would like to make some observations on how I believe our Federal science policy should be improved.

Progress in science comes from two basic endeavors, people who think, and people who carefully design and conduct experiments. There are two simple guidelines which, if understood and always taken into consideration, could make an immense improvement in the way the Federal government supports science.

First: The scientists are the "people who think". They should be selected and supported on the basis of the quality of their scientific work, not simply on how well they can write a proposal asking for support. When they are supported, they should not be burdened with preparing unnecessary progress reports, effort reporting and other unnecessary work which takes away the time in which they are to do their real work.

Second: Scientists must have the proper equipment in order to carefully design and conduct experiments. The equipment needed to keep scientific work at the forefront of scientific knowledge is much more

complex and more expensive today than it was in the past. Modern instruments are more accurate and often include computation capability which makes them much more efficient. It is a serious handicap for a scientist to have inadequate equipment and facilities for the work to be done. When the Federal government provides financial support for a scientist, it should also provide financial support for the equipment and facilities needed for that work. If it does so, it will get a better return from the work being supported.

These observations apply to people doing development as well as research. Experimental work for development would include testing to prove the integrity of the proposed design. Also, there would be drawings and instructions to produce models for eventual production. Computer aided design (CAD), computer aided engineering (CAE), and computer aided manufacturing (CAM) provide ways to greatly improve the productivity of development work.

I want to make some more specific recommendations on how the agencies can do a much better job in selecting the scientists they want to support.

I believe the peer review process is useful but it should not be carried too far. I have already said that the selection of the people to support should be based on their performance to the fullest extent possible. This implies that the peer review process should focus more on what the scientist has actually done, not just on what he says he can do.

I have seen many excellent proposals prepared by people who sound very credible but who have, in fact, had a dismal record in what they could actually do.

In our report on the Federal laboratories we recommended that each laboratory have a review committee and that the review committee should report not to the laboratory director but to the agency or organization responsible for the laboratory. It was intended that this review committee work would serve to reduce the number of routine reports required of the laboratory. An objective review of work done by a review committee of peers would be a much better way to evaluate the performance of a laboratory.

After a scientist, either in a Federal laboratory or at a college or university, has demonstrated good work, that program should be supported to provide long time stability for the work; no routine progress reports but a periodic evaluation of performance by the review committee should be made.

It would be very much better to reduce the peer review process at the beginning of a new program. If a mistake is made, it should be corrected in the performance review. Allowing a few mistakes would greatly encourage innovation.

Research at colleges and universities deserves continuing support, particularly what is generally known as basic research. Federal agencies and Federal laboratories find it difficult to place research contracts at universities because of the many detailed requirements placed on the contracting procedures.

All Federal agencies and Federal laboratories should be given specific authority to give contracts to colleges and universities on a sole source basis. There is absolutely no place for competitive bidding

for research placed with colleges and universities. This Committee could make an immense contribution to American science by obtaining support of the Congress to exempt research contracts placed with colleges and universities from competitive bidding requirements and with many other requirements such as small business, equal opportunity. These take time, add cost, and probably don't help much with the social reform that is intended.

I expect it is too much to ask the Congress to refrain from "log rolling" activities where research at colleges and universities is involved. It would be great if this work could be supported strictly on the basis of its contribution to the quality of American science.

Universities are also having a problem with the equipment and facilities available for their research people. The Federal government has done a fine job in the area of high energy physics where facilities costing hundreds of millions of dollars have been provided. There are many areas of science which may make a much more important contribution to our economic well being, the health of our citizens, and the quality of life than high energy physics. A few tens of millions of dollars for equipment and facilities would bring a big return in the productivity of scientific work in these other areas.

I would like to make a few comments about the tax credit for equipment given to colleges and universities by private sector business organizations. This arrangement has the advantage that most corporations give equipment to universities where quality work is being done and this is a positive feature of the program. Some corporations provide funds for installation, operation and maintenance, All should do so.

Corporate contributions are not all to the good, however, for some corporations use this as an advertising or sales gimmick. I would think that colleges and universities have received more personal computers than they really need and not enough of other kinds of equipment.

To give you a feel for the size of these contributions, the Hewlett-Packard Company has budgeted $45 million dollars worth of instrumentation, at list prices, to be given to colleges and universities this year. Our company is not at the top of the list, there are a few companies that do more.

Another problem with this tax credit program is that it does not extend to all colleges and universities on the basis of their real need. The tax credit program should be supplemented by direct grants for equipment by Federal agencies. The Federal agencies will receive more for their money if they take the responsibility for providing equipment where it is needed in the programs they support.

The Department of Energy has a special problem that needs to be corrected. The reason I am telling you about it is because you might be able to help. Our Committee on the Federal laboratories noted this problem and I have discussed it with two Secretaries of the department but the bureaucracy has refused to change.

The DoE treats research grants like contracts to do construction rather than contracts to do research. They have field offices that look over the work being done, they require monthly reports. This requires paper work by the ton. Most of it is useless and this poses a large and unnecessary

burden on the people doing the research work. They do this to the laboratories they support and they also do it to the people in universities doing research.

This problem came about because the Atomic Energy Commission was organized to be able to manage a large number of facilities construction programs. Here it was appropriate to have field offices to keep close control of the program. This apparatus was transferred to the DoE and it should be phased out. To do so would save many millions of dollars a year and provide an environment for the scientists involved to have more time to do scientific work instead of paper work.

I want to say a word about government owned - government operated laboratories like NRL, NBS, etc. Because these laboratories are under civil service regulations they are not able to hire, motivate or retain the best scientific people, scientists and engineers. Our laboratory committee recommended that these Federal laboratories be allowed to establish a better personnel management program. This could be patterned after an experimental program which has been operating at the Naval Ordnance Laboratory at China Lake in California. I visited this laboratory and discussed the program with the director. He has been able to improve the quality of his professional staff because of this program. I hope your Committee will support this program we recommended.

I note that the Department of Defense has proposed a similar program for all of the professional people in the department. I believe that would be a big step forward and I support their program. It may be difficult for the Congress to take the big step at this time but I hope they will at least

support the smaller step we are recommending for the Federal laboratories only.

All federally owned laboratories are not federally operated and one choice would be to put all of the laboratories under private sector management. I do not believe it would be wise to do so. I believe the present mix of federally operated and company operated laboratories is about right, but if the Federal government is going to operate a laboratory, it should be able to do so with a commitment to excellence and under policies that would encourage excellence. That is not the case today.

The Federal Laboratory Panel recommended that research people should be allowed to spend part of their time on ideas of their own choice. This would include areas of science other than that of their main program. We thought at least 5% of free time should be allowed, some Committee members thought it should be 10%. This idea is one that is supported by almost everyone who has had experience administering a scientific project.

This free time is probably the most important source of innovative ideas. Innovative ideas sometimes come from the laboratory director. Innovative ideas that contribute to the quality of American science never come from the Federal bureaucracy. Their "innovative ideas" almost always do the opposite.

The idea of independent research and development (IRD) for defense programs was originally based on an understanding of the importance of giving scientists and engineers some time free from their assigned work to explore their own innovative ideas.

This program was effectively destroyed by the "Mansfield Ammendment" in 1970 when the Congress required IRD to be limited to ideas related to military work. This required that the justification for IRD be documented to demonstrate the independent work had a military potential. While this requirement has been repealed, the practice has not improved very much. This country would receive much better commercial fall out benefit from the vast sums of money spent on military research and development if the original idea for having independent research and development were restored.

I hope some of these ideas will be useful to this Committee in its work to help assure that Federal support for science and technology will be as effective as possible. I know that many other committees of the Congress, probably too many, are involved in this issue. I believe, however, this Committee is in a good position to provide leadership and for that reason, I appreciate the opportunity to give you my recommendations.

I will be pleased to respond to your questions.

DISCUSSION

Mr. FUQUA. Thank you very much, Mr. Packard. It has been a very important and informative review of our Federal laboratories and basic research.

You mentioned toward the latter part of your statement about the time for innovative ideas, 5 to 10 percent of the time. That sounds like a novel idea. Is that a general practice in industrial labs?

Mr. PACKARD. Yes, I think it is. I recall 30 years ago when we were trying to learn how to manage the laboratory of our company that I looked into the ways of Bell Laboratories and General Electric and other companies were doing these things, and this is a common practice.

I think if you look at the source of innovative ideas that a lot of innovative ideas come from work that these people do that is apart from their main mission. I think it is pretty generally accepted that this is a very important, positive element in the administration of any research program.

Mr. FUQUA. When we look at the roles of the Federal labs besides their mission roles that they have and functions, should it be part of their goals to try to undertake programs that create better economic competitiveness, or should that just be left to the private sector?

Mr. PACKARD. Well, I think it is important for all of the Federal laboratories to have a mission that is well defined and that is important. One of the problems we found was that a good many of the laboratories were getting spread too thinly. They were doing things that were not always in their field of expertise. We also felt that these laboratories should make a better contribution to the productivity of our country, of industry, and we recommended, among other things, that closer relationships between industry and the Federal laboratories be developed.

We found that there was quite a variation in the practice here. There were some laboratories that had pretty much an open door to industry. One of the troublesome things we found was that some of the Japanese companies were taking more advantage of work done at the Federal laboratories than some of the United States companies. That was simply that the industry itself had not realized the potential benefits that could be obtained from establishing and maintaining a closer relationship with the Federal laboratories.

I think that matter is being handled better now. Many of the Federal laboratories have open-house programs inviting industry to come in, learn what is going on in the laboratories. They are cooperative programs. Certainly, I think that all of the Federal laboratories have an opportunity and perhaps an obligation, if you want to put it that way, to make contributions on a broader base other than to their specific mission.

The laboratories at Livermore and Los Alamos' primary missions are nuclear weapons, but they have a very broad range of scientific activity. They are doing work on the forefront of computer technology and in other areas where better communication with people in

industry could be a very important element in maintaining the leadership of our country in this whole field of scientific endeavor.

Mr. FUQUA. That brings on another question. What do you see as the role of the Federal laboratories at the present time and into the future? We are trying to look ahead for 30 or 40 years in our study. Where do you see the role of the labs from their present responsibilities to the future?

Mr. PACKARD. Well, it seems to me that you have got back, perhaps, to another fundamental proposition that there are certain things that the Federal laboratories can do which the private sector is not likely to do. Perhaps the private sector could do it, but I think the Federal laboratories do have an important position in the long-term picture.

The National Bureau of Standards is a good example. I think it is a proper Federal responsibility to have a standards laboratory to establish and maintain scientific standards that are provided for the industry. While industry can get together and sometimes does get together in establishing their own standards, it seems to me that this is a responsibility that is very important for the long-term picture. I think that kind of a job should be continued.

There are other areas where the cost of equipment, the cost of a research program is too great for industry to undertake this alone. I think that is another case where Federal laboratories will have a long-term position.

There are cases where the private sector has very little incentive to do things. High energy physics is a good example. There is no way in which you could justify the support of high energy physics which is very expensive as a long-term payout, so I think the Federal laboratories and the Federal Government has a role in that area.

There are other areas of research, for example, materials research. A good deal of research on materials is being done in private laboratories and at universities, but here again there are some areas where, for example, the synchrotron light sources are a useful device to investigate materials phenomena and probably too expensive for industry in general to support.

So, I think the role of the Federal laboratories is a long-term role. I might mention some of the defense laboratories and, again, although that is not in your area of responsibility, I think that over the years the Naval Research Laboratory, the Signal Corps Laboratory at Fort Monmouth, the Naval Ordnance Laboratory have provided in a sense a base of technology and a good coupling with the operational forces that gives a balance to the work that the private sector does.

So, I think there are a number of reasons why the Federal laboratories have been important in the past, and I think these reasons are going to continue to justify their importance in the future.

Mr. FUQUA. You mentioned on page 3 about the peer review process and that it should be based on a person's track record rather than just their ability in grantsmanship. That was my word, not yours, but I think we are talking about the same thing.

How would that impact the new researcher who is coming in who hasn't developed a track record over the years when we need

to provide some means to at least give that person an opportunity to prove himself?

Mr. PACKARD. In the first place, I think the peer review process at the front end still has some utility. I am not saying it should be discontinued. I am simply suggesting we ought to change the emphasis.

There are clearly cases of young scientists who do not have a track record. There they have no alternative but to put a proposal together and somebody knowledgeable should review that proposal and make some estimate about the desirability of supporting it.

I think there are many cases where the laboratory director could recommend that some of his newer and younger research people be supported. Quite often, his judgment would be, I think, just as good as the judgment of a peer review committee.

Also, as I have already mentioned, I think you could be a little bit more open in these programs and maybe not be quite so critical in evaluations and just take a few more chances, give some of the young people who come up with an idea a chance to try it out without having to get a full-fledged peer review committee to approve it. I think in doing that, you might make some mistakes, but in the end, you might come out just as well.

So, what I am suggesting is that we have a little more open process and don't get tied to such official specific routines and regulations. I think a little more openness in the whole thing would result in a better outcome.

Mr. FUQUA. When we were talking earlier about the 5 to 10 percent creative time, should that be included in the overhead costs to, say, universities?

Mr. PACKARD. I think that would simply be included in just a sort of informal allowance. The research support would be for the scientists or engineers' salaries and operating expenses. Those are really direct costs, not necessarily overhead costs.

I think you just give them a little flexibility in saying you don't have to spend all your time on this specific mission and you wouldn't have to have a lot of detailed tracking of that. You would let the laboratory director sort of handle that program, but it would be important that the Congress and particularly the committees which are responsible for this understand that this is being done so that if they heard some fellow got a little too much free time, they could support it.

I don't think you need any increase in the overhead to do this. It would, I suppose, in effect increase your overhead rate a little bit because you would have a little bit smaller direct base on the mission part of the program, but I wouldn't put any stringent rules and regulations on this. I think just indicating to the laboratory director that this is expected of them and let them work out the negotiations on a case-by-case basis.

Mr. FUQUA. One of the inherent conflicts that we are always confronted with—I know I have people talk to me about it—is that sometimes there is the desire on the part of some of the Federal laboratories to conduct basic research that could just as well be done in university laboratories or maybe a private research institution. How do we ensure that the Federal labs are not usurping the rightful prerogatives?

Roland Schmidt, the Chairman of the National Science Board, was sitting where you are a few weeks ago and was talking about the colleges and universities where we train scientists, and then you apply them when they go to work for your company or a Federal lab and some of those, but we must not ever take our eye off the fact that the colleges and universities are where they are trained. To do that, of course, they need a certain amount of basic research and the instructors and professors need that.

Is that—there is probably going to be a continuing conflict, I guess, but I would appreciate your comments on that.

Mr. PACKARD. In the first place, I think it is very desirable for any laboratory of any size to do a certain amount of basic research, because this sort of gives the leavening to the program and gives some interesting things for people to be working on. So, I don't think the Federal laboratories should be prohibited from doing basic research. I think they should do a certain amount of it themselves.

The problem is one I have already indicated that the rules of contracting which are imposed on these Federal laboratories require, in general, that they require competitive bidding for research they place at universities. That is exactly the wrong way to do it.

They can, the laboratory director or their purchasing people, get exemptions from this competitive bidding, but it is a lot of work to do. They have to justify it to somebody, and it is just a whole lot easier, in many cases, to decide we will just do this ourselves.

I think it would be very helpful if this committee and the Congress could make a clear position on this matter that the Federal laboratories should be encouraged to place basic research contracts at universities on a sole source basis.

What you want to do is you want to identify a scientist or an engineer or a group of scientists or engineers who are working on a problem that is of some interest to the laboratory and identify those people who are doing some good work and give them a chance to support their work. To put it out to competitive bidding, and to put all these other requirements on these contracts is the thing that is just too much trouble for these guys to do it, and that ought to be fixed.

Mr. FUQUA. Mr. Ritter.

Mr. RITTER. Thank you, Mr. Chairman.

Mr. Packard, I regret—is this on? It is typical that at a Science and Technology hearing, the microphone doesn't work. No, it is not typical actually.

I regret, Mr. Packard, that I spent the first half hour of your testimony on the rain-soaked road coming in from National Airport in a taxi whose driver refused to pass anybody else. We were at the back of the line, and it was somewhat frustrating.

However, I have followed your work on the Packard Commission quite closely as part of this Science Policy Task Force and also as vice chairman of our Republican House Task Force on High Technology Initiatives.

In previous hearings on the Federal and national laboratories, it was pointed out that while there have been strong missions for a number of these laboratories in the past—very defined missions—

that the current state is a more uncertain one and that there is some seeking of mission to some extent, some drift within certain national and Federal laboratories.

A number of us here are interested in the whole idea of industrial competitiveness. From both sides of the aisle, there was discussion about trying to modify some of the more uncertain missions toward a mission of, broadly speaking, enhancing industrial competitiveness and making the requisite changes within the system in order to fulfill that mission.

Do you have any thoughts on that matter?

Mr. PACKARD. I think this is an important point. I think the Federal laboratories should be encouraged to find some missions that will make a contribution to the overall welfare of our economy and society. It might be competitiveness; it might be other things, too.

One of the difficulties we found was that in all the concern about our energy shortage, there had been a lot of ideas that were being pursued that were not very practical. Some of the laboratories tended to get a very broad range of things they were doing. We felt it would be better for them to develop some expertise in specific areas, and that is really where the idea of missions came about.

In looking at the question of what the laboratories might do to help with our competitiveness, there were several things that came up. Specifically, if you look at almost any area of science and technology, we are limited in what we can do by our knowledge of materials. This is true in electronics, it is true in aviation, it is true in the automobile industry, it is true in almost anything else.

One area that we thought should be emphasized would be to have the Federal laboratories have a stronger role in the field of materials. This is the kind of area that I think should be encouraged.

As you know, there is a great deal of interest in supercomputers. Supercomputers have limited utility in the overall competitiveness of our economy. They have been utilized for rather special things such as weapons design and a few other areas. With the trend in computer technology, with the capability of the performance going up and the costs coming down, it is very likely that supercomputers will have a much larger, much broader role in industry in doing some things that simply weren't done before.

Here, the Federal laboratories, Livermore Laboratory, for example, and some others are doing some work in this area, and they are making it available to business and industry with some communication both ways. So, I think there are already some things that are being done that will enable the Federal laboratories to make a more important contribution in areas that will help our long-term competitiveness of our economy.

Those are just a couple of examples, but I think this is something that should be encouraged.

Mr. RITTER. Do you envision any need for adapting the steering mechanisms of some of the Federal and national laboratories so that there is somewhat of a privatization of the research directions, or do you feel that this will settle out by itself?

Mr. PACKARD. What we essentially recommended was that these laboratories should have a review committee of professional people, scientists, and engineers, and probably some business people, too,

that would monitor the progress of the laboratory, make recommendations as to what fields they should enter, and generally supervise them and monitor them on the basis that they should develop programs of excellence in whatever they do.

I think that kind of an approach, by allowing people from the private sector to participate in these laboratory committees, would probably in the long term result in a better choice of program than, for example, trying to have the Congress sit down and decide what ought to be done or to put some arbitrary rules on it.

I think that the extent to which you can encourage the laboratories to concentrate on the mission—concentrate on building excellence in whatever they are doing—and open communication with the private sector, and particularly with a review committee that would evaluate performance and report to the mission agency or whoever is managing the program, that this sort of a little bit more flexible arrangement would be much better than trying to sit down and decide this laboratory should do this and this will do that and so forth.

There are certain exceptions, of course. In the defense laboratories, they have to work on nuclear weapons and there are specific areas in defense where you maybe want to have a laboratory targeted for a defense objective, but I think for the laboratories this committee is working with, it would be very desirable to have an emphasis on encouraging them to make a contribution to the productivity and the quality and so forth of our economy.

I think to do it on a broad basis with getting expertise in to spend some attention, pay some attention to each individual laboratory is the way to go. And I think that is already being done to some extent. I think there is a good start being made, and I would simply encourage what is already being done.

Mr. RITTER. There is a general consensus that energy is not the crucial mission that it once was. At one point, we had AEC laboratories. At the next stage, we turned them into Energy Department laboratories in order to solve the energy crisis or to approach the energy crisis. But I think it is fairly well accepted that these days we don't have an energy crisis, yet we have a need to justify a variety, a whole wide range of programs, on an energy basis. Eventually, that has to be the justification.

Do you sense that some moderation of the direction of the mission within the Energy Department or to somehow find some other umbrella might help in targeting the resources a little more closely toward the needs?

Mr. PACKARD. If I understand your question, I think there are essentially two sides to this problem. There are certain laboratories that, for valid reasons, are going to have a fairly specific mission. I think it would be desirable for those laboratories to become involved in a certain amount of activity that is related to their mission but not strictly on it.

In other words—well, you have this going on already that the Lawrence Livermore Laboratory is doing some work that is not defense in areas where they have developed a great deal of expertise because of the defense activity. That is true, I think, of Los Alamos to some extent. You are going to hear a little bit more about that, I guess, this morning.

The other side of the coin is that there are a number of laboratories which originally had missions. Argonne is a good example. They were in on the very development of nuclear energy and had an important role. They were sort of overtaken by developments otherwise, and they ended up without a very strong position in their original field.

It seemed to us that it would be desirable to encourage all of the laboratories to develop some special expertise which we call their mission and thereby try to develop a program of excellence. This, we felt, would be much better than the alternative which would seem to be the case when a laboratory is simply going on trying to find enough work to keep it busy. There was a lot of that going on. The director had a certain level of people, and he felt an obligation to keep them going, so he would go around and find any old job he could do, in effect, to keep the program together.

That seemed to us to be not the most effective way to utilize these resources, so this idea of a mission really came about from the fact we thought the laboratories should be committed to developing a field of excellence that they had a little special expertise in and then the way this expertise would be utilized would depend on what the field happened to be.

Mr. RITTER. But if that field is overall energy, doesn't that somewhat limit the innovative aspects in approaching new missions to the tail of the dog or the periphery of the field?

Mr. PACKARD. Sure, it does if you make the requirement for a mission too tight. I think——

Mr. RITTER. In other words, I guess my question is, is the Energy Department set up to accommodate the shift from what used to be AEC and then an energy crisis to a kind of crying need to have some U.S.-style MITI's in our midst?

Mr. PACKARD. I think they should have some flexibility and it could be and probably will be that over the years the mission could change, that they find they are getting involved in some new idea.

One of the important things, I think, is you find a line being too concentrated and too dispersed. You need some concentration in order to build up a position of excellence. You need a little flexibility in order to look at ways in which this excellence could be applied in innovative ways. So, you need some flexibility.

I guess the best answer is that it ought to be not one way or the other; you ought to steer a course somewhere in between.

Mr. RITTER. Mr. Chairman, I have one other brief question, but I would like to yield back to you because I have taken some fair time here.

Mr. FUQUA. Go ahead. We still have three more witnesses, however.

Mr. RITTER. OK. The last question and briefly, are you satisfied with the Federal response to date of the recommendations of the White House Science Council study which you chaired on Federal laboratories?

Mr. PACKARD. The answer is no. I think you know the history of most of these commissions. They make their recommendations and, quite often, they are filed away and no one pays any attention to them.

I am encouraged by the fact that there has been some positive response. There have been established some supervisory committees along the lines we have recommended. There have been, in some of the laboratories, an increase in the amount of free time they are allowing their research people. I think, in general, there has been some encouraging response.

We had a review of this about a year or so after the Commission report was made, and I was encouraged that people had paid some attention to the report and had done something about it.

I am disappointed in the response we have had on this recommendation to get the wage and salary administration out from under the Civil Service regulations. That was a matter where I thought we had the support of all the key agencies, the Department of Defense and NASA and the other people who all thought this was a great idea. It got into the bureaucracy and took about a year and a half and got completely turned around. So, I wasn't satisfied with that. I am delighted that your committee is taking a positive position on this, because I think that is an important contribution.

So, the answer is I am not satisfied, but I think we did have some fairly good response to the recommendations that we made.

Mr. RITTER. Thank you, Mr. Packard.

Thank you, Mr. Chairman.

Mr. FUQUA. Thank you, Mr. Ritter, and thank you very much, Mr. Packard. We appreciate your taking your time to be here with us. You certainly come from a background that can be very helpful to us, and we thank you very much.

Mr. PACKARD. Thank you for the opportunity.

Dear Mr. Packard:

Thank you for your excellent testimony before the Science Policy Task Force on October 22, 1985. Enclosed are a number of questions that Members of the Task Force would like you to answer, in order to supplement the record of the hearing.

We would appreciate your responses to these questions by November 15, 1985. If you have any questions regarding this request, please contact Dr. Harlan Watson of the Task Force Staff at 202/225-4320.

Sincerely,

DON FUQUA
Chairman

QUESTIONS FOR THE RECORD

HEARING ON "Science in the Mission Agencies and Federal Laboratories"

TASK FORCE ON SCIENCE POLICY

October 22, 1985

Mr. David Packard

1. Do you anticipate that without a personnel management program similar to the experimental one at the Naval Weapons Center that Federal laboratories will have a shortage of quality technical staff?

2. Facilities and equipment for science are expensive. How can Federal agencies with decreasing or stable research budgets fund facilities and equipment at universities and Federal laboratories without taking funds from researchers? How do industrial research organizations handle the tradeoffs among facilities, equipment and researchers?

3. What should be the policy toward establishing new Federal laboratories and reorienting existing facilities?

4. Among the government-owned, government-operated laboratories, what criteria would you apply in deciding which laboratories should remain under civil service regulations and which laboratories should "be allowed to establish a better personnel management program"?

5. It is claimed that basic research in industry is nearly non-existent. How dependent is industry on the Federal Government for basic research? What would motivate industry to increase its basic research activity? Is the perceived compartmentalization of research by government and academia and development by industry necessarily bad?

RECEIVED
NOV 25 1985
COMMITTEE ON SCIENCE
AND TECHNOLOGY

HEWLETT-PACKARD COMPANY
1501 PAGE MILL ROAD
PALO ALTO, CALIFORNIA 94304

DAVID PACKARD
CHAIRMAN OF THE BOARD

November 21, 1985

The Honorable Don Fuqua
Chairman
Committee on Science and Technology
Rayburn House Office Building, Suite 2321
Washington, D.C. 20515

Dear Chairman Fuqua:

I am pleased to answer the questions you raised in your letter of October 24th. I apologize for the delay in responding but I am arranging to send this letter by special messenger with the hope that you receive it in time for further deliberations of the committee.

1) I believe that without a personnel management program similar to the experimental one at the Naval Weapons Center that Federal laboratories will have an increasingly severe shortage of quality technical staff. The quality of staff who run all these laboratories is already beginning to deteriorate and the situation will certainly become worse unless this constructive action is taken.

2) I believe the objective of Federal support for research should be made as effective as possible and this can not be done without providing some funds for facilities and equipment in addition to personnel costs. I am quite sure that if some of the other recommendations I made were followed, particularly those relating to the elimination of unnecessary paper work, that more funds would be available which could be applied to facilities and equipment for the work being supported. In a good many cases research people are able to get funds from industry and other sources, but in doing this it always takes time away from the important research work. One idea which might be helpful would be for the Federal government to provide funds on a matching basis. This would help because it is doubtful the Federal government would be able to meet the entire needs of facilities and equipment and a matching program would help.

I have taken the liberty of asking a friend of mine, Franklin M. Orr, Jr., who is doing important research work at Stanford University funded by the Department of Energy, to respond to this question and a copy of his letter is attached for your information.

Industrial research organizations always consider the need for facilities and equipment in authorizing research programs. Our company, for example, would not think of authorizing a research program in our own laboratories without making sure the facilities and equipment necessary are available. This, of course, means that the total cost of research is more than the cost of personnel, and I am quite sure the Federal government would get a better return from the dollars they spend on research if the facilities and equipment problem was considered as an important part of obtaining good research.

3) I believe new Federal laboratories should be established in the future only when there is a new important mission identified that is not being effectively handled by existing laboratories. This is a basic approach already used in high energy physics, astronomy and a few other areas, but I think there are not likely to be many requirements for new Federal laboratories. I think it would be very desirable to consider the possibility of reorienting existing laboratories when new missions are identified, particularly to the extent the talent and facilities of existing laboratories could be adapted to the new mission.

4) Although our Federal laboratory study committee did not visit all of the government run, government operated laboratories it was our impression that they all would benefit by being allowed to establish a better personnel management program. The basic criteria should be whether or not they are able to attract, motivate and keep a high quality professional staff. Many Federal laboratories have a certain prestige which helps them to attract and keep a good professional staff, but the salary differentials between government operated laboratories, other laboratories and industry, have simply become too large to assure that government operated laboratories will have highly trained and highly motivated staffs in the future.

5) Basic research in industry is being done extensively in some industries, although the universities and the government do a much larger share.

In the electronic industry the research laboratories of the General Electric Company and the Bell Telephone Laboratories did a great deal of basic research in the early days before World War II. Other large organizations such as IBM also support basic research. Du Pont and other companies in

in the chemical industry have had strong programs in basic research over the years, but at the same time it is true that some industries do very little basic research. I think the tax credit for research and development is a positive factor in encouraging industry to support more basic research even though the larger part of industry research is directed toward specific new product development. I do not believe the compartmentalization of research by government and academia and development by industry is necessarily bad. I believe what is needed is more communication among the organizations doing research, and I believe communication among the participating parties has increased substantially over the last few years. The Federal laboratories have a number of programs which enable industry to learn what the laboratories are doing and to obtain help from the laboratories in their own research programs. Industry is supporting a great deal of research at the universities all across the country, and in doing so they are increasing the communication between universities and industry.

The only basic recommendation I could make would be to modify the tax credit for research to allow it to extend to basic research supported by industry at universities and other independent research organizations.

I appreciate the opportunity to express my views on the important work your committee is doing.

Sincerely,

David Packard

Mr. David Packard
Chairman of the Board
Hewlett-Packard Company
1501 Page Mill Road
Palo Alto, CA 94304

Dear Dave:

I have the following observations on the questions raised by the House Committee on Science and Technology:

Question 2. Facilities and equipment.

There is no question that facilities and equipment are expensive. One of the central problems facing an academic scientist and his department chairman and dean is to find the resources to provide laboratory space and the equipment to allow the researcher to work at the forefront of the field. In some areas, it now takes more money to equip a high quality lab than it does to endow the faculty position the equipment is meant to support. There is no simple solution to the problem. No doubt university faculty and administrators will continue to struggle with it for a long time.

There could be improvements, however, in the way funding of research is handled. As you know most of my experience with Federal funding is with the Department of Energy. A recent request for proposals, to which I responded, contained the statement that the research organization "is expected to furnish all property (including but not limited to facilities, equipment, special tooling and material) necessary for the performance of the work defined in this solicitation." I responded even though the equipment I need is not available now, in effect committing to find other sources for the funding required. The funding was awarded, and hence, I have spent much of the last month trying to raise funds from oil industry. Thus, instead of working on our research I am spending significant portions of scarce research time on additional fund raising. To me it seems that recognition by DOE that research costs are a mix of equipment and personal costs would be much more sensible. To be sure, in an environment in which total funding is fixed funding of some equipment and facilities would reduce funds available for other costs. It would be better, I think, to fund some work adequately, including equipment needed, rather than supporting only noncapital costs for projects without adequate equipment. If funds are limited, as they always are, then it would be better to fund the true cost of the research than to ignore the equipment side. Industrial laboratories, for example, have no choice but to provide funding for the full cost of research they undertake.

Question 5: Basic Research.

This question is hard to answer because it is hard to define basic research. If basic research is only that which has no practical application, then it is probably true that basic research in industry is limited. That definition seems too restrictive to me, though. There are many industrial research organizations that investigate underlying physical principles because they need to understand the physical behavior to design products and control processes. The oil and electronics industries offer many examples of high quality research in support of commercial objectives. The Federal government, particularly NASA and the Department of Defense, has also had a significant role in supporting relatively fundamental research performed in industrial settings.

It seems clear that there is definitely a need for some support for really long-term research, for which immediate applications are not yet apparent, because none of us are very good at foreseeing what will and will not be useful eventually. That work probably ought to be done mostly in universities, and the support should probably come mainly from the National Science Foundation and other Federal sources.

There is also a need for applied work in universities. Many graduate students will eventually work in industrial research organizations, and they and the organizations benefit from graduate research on problems with some connection to practical applications, however tenuous.

It seems to me what is needed is a reasonable overlap between the work going on in industry research organizations and academic laboratories. With adequate communication, each will stimulate the other. It makes sense that university research lean toward longer term research and underlying, unifying principles, with specific applications being pursued more heavily in industry. Industries with vigorous research programs are, of course, best equipped to take advantage of work done in universities and to have some impact on the problems attacked by university researchers. Thus, I do not think that strict compartmentalization is desirable. I am not sure how industry can be persuaded to increase its research activity except to argue that in many industries, competitiveness in the long term is strongly influenced by the quality of their research effort.

I hope some of this rambling is useful. I think the country would have a more productive national research if the recommendations you made recently were adopted. Those of us in the trenches thank you for trying.

Sincerely,

Lynn

Franklin M. Orr, Jr.
Associate Professor

/aeo

Mr. FUQUA. Our next two witnesses will be Dr. Eugene Stark, Industrial Initiatives Officer at Los Alamos National Laboratory and Chairman of the Federal Laboratory Consortium which is made up of over 325 Federal R&D labs and centers; and following Dr. Stark will be Dr. Will Hess, Director of the National Center for Atmospheric Research. Dr. Hess has broad experience in the Federal Establishment and served as both a research scientist and administrator with the Atomic Energy Commission, NASA, and NOAA.

Dr. Stark, we will begin with you. When you have completed, we will hear from Dr. Hess, and then we will have some questions.

[A biographical sketch of Dr. Stark follows:]

DR. EUGENE E. STARK, JR.

Chairman, Federal Laboratory Consortium for Technology Transfer.

Professional position: Industrial Initiatives Officer, Los Alamos National Laboratory, Los Alamos, NM 87545, Tel. (505) 667-4960.

Dr. Stark was born and raised in Miami, Florida. He was educated at MIT in the Department of Electrical Engineering, receiving B.S. and M.S. Degrees in 1969 and ScD in 1972. He held an NSF Graduate Fellowship, 1968-1971, and a Hertz Foundation Fellowship, 1971-1972. He participated in a co-op program at IBM, with two summer assignments at the System Development Division and one six month assignment to the Thomas J. Watson Research Laboratory.

He joined the Los Alamos National Laboratory in 1972 in the Laser Fusion Program. He participated in experimental and theoretical laser research and development and held Deputy Group Leader and Project Leader positions in that program.

During a two year assignment to the Director's Office staff, 1974-1976, he developed a technology transfer program for Los Alamos and has headed this effort ever since. When Los Alamos joined the Federal Laboratory Consortium in 1975, he became the Laboratory's representative; he became Mid-Continent Regional Coordinator in 1977, and was elected Chairman in 1980.

His present responsibilities at Los Alamos include technology transfer; the development of institutional goals, and implementation of strategy for cooperation with industry; and fulfilling the functions of the Office of Research and Technology Applications mandated in the Stevenson-Wydler Technology Innovation Act. He received a Distinguished Performance Award from the Laboratory in May, 1985.

He is a member of the Boards of Directors of the Los Alamos Economic Development Corporation, the New Mexico Technological Innovation Program and the New Mexico Industries Development Corporation.

STATEMENT OF DR. EUGENE E. STARK, JR., INDUSTRIAL INITIATIVES OFFICER, LOS ALAMOS NATIONAL LABORATORY, LOS ALAMOS, NEW MEXICO; AND CHAIRMAN, FEDERAL LABORATORY CONSORTIUM

Dr. STARK. Thank you very much, Mr. Chairman.

I am pleased to have this opportunity to discuss some issues related to the future of science as requested by this committee, in particular, in the areas of the roles and missions of the Federal laboratories, R&D coordination, and also the role of applications in strengthening science.

I would like to begin with what I think is an important underlying perspective, and that has to do with the key role of the technical leader of a Federal laboratory, whether his title be director, technical director, or chief scientist. I think we would all agree that that job is a very challenging one, but perhaps the greatest responsibility of that leader of a laboratory is in maintaining the morale and productivity of an excellent technical staff. It is all the more important because that responsibility and performance is one

that is very difficult to measure, and I believe that responsibility makes some of the more quantifiable measures of a laboratory director's success pale in comparison.

My point then is that given a general role of Federal laboratories, a mission for that particular laboratory and program assignments, the agencies or operators with cognizance over that laboratory should support, not manage, those technical leaders. They already have and cannot really share with those outside the laboratory the very important ability to, as I said, influence the productivity and morale of their staff.

Turning now to the role of Federal laboratories, I think fairly generally it is to attract, retain, and support the best scientists and engineers who choose to work for Federal laboratories in basic and applied research, development, engineering, and testing as desired by the Government.

There are several specific attributes that make the Federal laboratories from other research performers. First of all, many of them span the spectrum from basic and applied research all the way to development and engineering and, in some cases, applications. It is very important because many of the specialty applications or programs assigned to Federal laboratories are much more applied science than they are engineering or development. For that reason, these applied scientists need a direct infusion of information and ideas from basic research. Furthermore, those engaged in applied science need to maintain currency, renewal, and the intellectual stimulation that comes from close cooperation with those performing basic research.

Second, I believe the Federal laboratories are important institutional complements to universities and industry. They are institutions where basic and applied research can be undertaken without heavy teaching loads or any teaching load. On the other side of the coin, they are able to undertake applied research and engineering on much longer range and riskier programs than may be available to industry.

The laboratories, therefore, provide, if you will, a third sort of choice for careers for scientists and engineers, allowing individuals to fit themselves best to the institutional opportunities. Furthermore, this additional opportunity for employment strengthens the whole technical community.

Another role of Federal laboratories is that multidisciplinary and team approaches to research can be much more easily done there in many cases, because of the breadth of their organizations, the fact that there may be less disciplinary barriers, and there is quite a bit of staff flexibility that may permit staff that began as a physicist or a chemist to do engineering or vice versa during his career.

Another role is that the laboratories can maintain long-term Government programs with the assignment of top quality staff specifically because those long-term programs can be the prime mission of their organization.

Finally, some other roles include the maintenance of major experimental facilities, maintaining major technology bases for the Government, and also the fact that at least their unclassified results are fully publishable. There is no proprietary information within the Federal laboratory system.

Turning now very briefly to the mission issue within Federal laboratories, I think it is fair to say that several of our Federal laboratories are the largest R&D institutions ever to exist in this world and, to some extent, we are therefore learning by doing. But any such institution has to have a unifying primary mission that permeates the entire organization and creates a strong institutional culture. This mission should be reviewed on a regular basis and, if there are changes contemplated to a laboratory's mission, they should be changed carefully but also changed rapidly in order to avoid what some will call mission malaise but, in particular, to maintain the most excellent technical staff and particularly the motivation of that staff.

Many laboratories, of course, have secondary missions that may involve areas such as education or technology applications. These secondary applications should be led or spark-plugged, if you will, by individuals carrying a careful balance between those secondary missions and the primary mission and, wherever possible, contributing strongly to the primary mission of the laboratory.

I was asked to address the possible contribution of our Federal Laboratory Consortium to R&D coordination among the Government labs and between the Government labs and outside research performers. Very briefly, since some may not be familiar with the Federal Laboratory Consortium, I will describe it.

We have as members of this Consortium about 350 Federal laboratories from 11 agencies. We are responsible for about 85 percent of the Federal Government's in-house expenditure of R&D dollars. We network together in basically an interpersonal network to make for better accessibility of Federal technology to outside users. This work includes development and replication of methods of outside cooperation, training of individuals, recognition and promoting awareness of the value and availability of Federal technology on the outside.

Returning to the primary issue, this is a very important one because it strikes to the best use of technical resources in this nation, not just governmental, but all science and technology resources. I would suggest as an umbrella for this discussion collaboration to mutual benefit, both on a personal and institutional basis.

Collaboration provides much stronger support to both Government and nongovernmental efforts, renewal of individuals, and sharing of ideas. It is very important in the science and technical communities.

First of all, a bit of a perspective. Between the Government and the outside, any such collaboration needs to be initiated by the outside. It is not terribly credible for the Government or Government laboratories to be marketing their resources blindly to the outside. However, the laboratories need two things. They need pragmatic accessibility to their technology by the outside, and, even more importantly, the outside organizations need to have an awareness of the value of Federal technology, Federal science, and of that accessibility.

Within the Government itself, R&D coordination is really the responsibility of the laboratory director. In both cases, however, what may be needed is a strong network of support, communication, and cooperation with a very active can-do attitude.

Now, my answer to the original question as to whether the Federal Laboratory Consortium might contribute to this is yes, indeed, and we are doing some of this already. Particularly, if this were added and made an additional mission of our Federal Laboratory Consortium, we would be pleased to assist here. Going back to the initial philosophy that I mentioned, this would be done as a support service to laboratory management, not as something to be imposed on them from above.

To give, briefly, some very important examples of this, within the laboratories and our Federal Laboratory Consortium, we are developing on a trial basis expertise, data bases, so as to make it more easy for us to understand what is going on in other Federal laboratories, electronic mail systems from stronger communication between technology brokers and research brokers, if you will, at the various Federal laboratories, as well as developing and strengthening methods for cooperation and transfer among the Federal laboratories.

We are also working to, if you will, organize the external research community. We have already a university common interest group which involves a steering committee from a number of universities around the nation who are trying to organize the university community so as to have a better access to the Federal laboratories.

Based on some detailed studies we have done in the last few years, we will be soon initiating detailed common interest groups with large and small business as well as with trade associations.

Examples of the efficacy of this approach include the fact that in cooperation with other organizations, we work to sponsor conferences in which Federal laboratory people meet and learn to cooperate directly with industry people. Fairly recently, there was a set of such conferences in Philadelphia focusing on materials technology and in biotechnology. We at the FLC have formed basically the only interagency communication network on technology transfer, our agency liaison group.

Researchers at the Army's Harry Diamond Laboratory who, a number of years ago, initiated so-called fluidics technology and began to find that work in that area was springing up in industry as well as in the Navy and the Air Force took the lead in developing a coordinating committee on fluidics research so that people would know what each other were doing. Again, this was not a function mandated from above but driven by the individual researchers' interested in knowing what others were doing and avoiding any kind of duplication of effort.

Finally, I would like to address briefly the role of applications in strengthening science. I am well aware that it is not an intention of this task force to look in detail into the applications of science or into the innovation process, but I think it is important to note that this entire chain from basic research to applications is not a one-way chain. Strengthening the applications can turn around and strengthen basic science very strongly.

It is clear that those applications are very important to our society, from the extremes of defense to the strengthening of our economy through the productivity of State and local governments, local economic development initiatives, innovation and assistance to

small and large business, and ultimately to our national economic competitiveness. I feel that a stronger full chain from basic research all the way through applications will strengthen science in at least three ways.

First of all, the public will increase its support by seeing that the applications of science are undertaken in a systematic way rather than seeing only anecdotal results. After all, the best ideas cannot be kept hidden even if we try to keep them from commercial application. We need stronger systems to make sure that they are applied.

Second, a stronger chain will draw more talent into science and engineering, particularly within the Federal laboratories, as young people see better opportunities for themselves and a broader range of career opportunities in science and engineering, even including entrepreneurial spinoffs, whether it be from a Hewlett-Packard or from a national laboratory.

Third, applications do provide direct technical benefit right back to basic and applied science, on the one hand, through providing state of the art excellent low cost instrumentation and on the other side, providing some problem identification from the real world which can strongly inspire some areas of basic research.

In the specific case of the Federal laboratories, I feel that collaboration with the outside world can provide not only strong applications which strengthen science, but also very strong benefits right back to the mission of the Federal laboratories. Second, there is still the issue of accessibility to the laboratories for rapid applications requiring that there be stronger mandates, full-time people, active programs, and particularly decentralized authority and responsibility within the laboratories.

The awareness issue is still a difficult issue. Much of American industry still does not understand that laboratories have something that can be useful to them and understands far less that they are truly trying to be accessible. We are working very hard to change that through contacts with industry, with trade associations, with other common interest groups such as the U.S. Conference of Mayors. The basic difficulty here is that it requires individual networking to convince people outside the Government that there is something inside the Government that can be useful to them.

I think my bottom line on this subject is that strengthening the payoff of science will clearly strengthen the basic science from all standpoints of support to availability of manpower.

Again, I would like to thank you for this opportunity to address the task force, and I would be pleased to answer questions when the time comes.

[The prepared statement of Dr. Stark follows:]

STATEMENT

before the

COMMITTEE ON SCIENCE AND TECHNOLOGY

U.S. HOUSE OF REPRESENTATIVES

Hearing on

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORTORIES

October 22, 1985

Eugene E. Stark, Jr. Sc.D.

Chairman, Federal Laboratory Consortium for Technology Transfer

and

Industrial Initiatives Officer

Los Alamos National Laboratory

Mr. Chairman,

I am grateful for the opportunity to present some views and perspectives on science in the Federal Laboratories. As requested, I will focus this statement on issues of R&D coordination in the Laboratories, changes in mission, Laboratory roles in the research community, and several additional issues that may be important in this context.

I am appearing today in my capacity as chairman of the Federal Laboratory Consortium for Technology Transfer (the FLC). This is the only organization that involves virtually all major federal R&D facilties. One unifying theme in these remarks is that the inter-Laboratory cooperation that characterizes the FLC can be a major factor in strengthening both the Laboratories' mission programs and the use of their expertise and technology in the American economy.

AN UNDERLYING PHILOSOPHY OF LABORATORY LEADERSHIP

One distinction that can be made between basic science and engineering is that innovation develops from the bottom up in scientific institutions, whereas major engineering achievements are often driven by top management. Research is performed, often self-motivated, by the individual researcher. The morale, productivity, and recruitment of good scientists and engineers is ultimately the greatest responsibility of the Laboratory technical leader, whether the title is Director, Technical Director, or Chief Scientist. The leader's performance in this arena is the most critical of his functions, and yet is the most difficult to measure.

The government's role should be to assign clear missions and project responsibilities to the Laboratories and then to support each Laboratory's leadership in fulfilling these assignments. It may be a subtle distinction, but an important one: Through his ability to influence the Laboratory's culture and the performance of its individual technical staff members, the leader already has the bulk of the authority needed to determine the Laboratory's health and performance; other Agency interactions should support, not manage, the Laboratory's leader.

As one example of the efficacy of this approach, the Department of Energy's Office of Military Application has the smallest headquarters staff per program dollar expenditure of any technical program organization in the government. It gives broad direction to the DOE weapons laboratories, which have the responsibility and stewardship to fill the nation's needs in nuclear weapon development.

R&D COORDINATION

The Task Force on Science Policy has raised the issues of coordinating effort between government and non-government R&D organizations and of preventing unwarranted duplication of efforts within the Federal Laboratories. In particular, it was suggested that the Federal Laboratory Consortium for Technology Transfer (the FLC) might have a role in these areas. (For completeness, the FLC is described briefly in an attachment to this Statement). These questions are related but should be approached quite differently.

Coordination of R&D efforts of the Federal Laboratories with other private and public research organizations can be viewed as an effort to collaborate to mutual benefit. For those individuals conducting open research (i.e. neither classified nor proprietary), it is a professional responsibility to maintain an awareness of similar work in other organizations, and to collaborate when appropriate. Much of this technical "networking" occurs in basic science, but this is much more difficult for individuals engaged in the more applied areas of research because of the large number of related projects, institutions, and results that can advance faster than the technical literature can track. In this area, the national networking of the FLC is increasingly putting private and public organizations in touch with the Laboratories and the individuals working in their areas of interest. It is particularly important that the aspects of technical networking be driven by non-federal organizations: Cooperation initiated by these outside researchers or organizations is motivated by their internal needs or perceived opportunities. The Federal Laboratories have an obligation to be accessible to these requests but the Laboratories have no reciprocal right to request, for example, access to companies' proprietary research.

The issue of duplication of effort is a bureaucrat's nightmare, but there is no evidence of major unwarranted duplication in the Federal Laboratories. A broader question that includes this issue is that of making the best use of available federal expertise and facilities. Again, the FLC provides a support service to the Laboratories by brokering and networking a Laboratory's need for access to certain facilities or expertise of other Laboratories.

In both areas addressed above, the outstanding leaders in Federal Laboratories will want to pursue networking and cooperation with other federal facilities and other research organizations. The FLC's present informal role in this arena could certainly be strengthened, but it should work in these areas only in support of the Laboratory leaders, never to be imposed on them. Or to take an alternative viewpoint, cooperation and avoiding duplication are sufficiently important to a Laboratory's strength that the Laboratory's efforts to do so should be supported rather than dictated.

The FLC is working in several areas that are strengthening its capability to provide this support. Its Far-West Region is constructing a prototype Laboratory expertise data base, to be used for inter-Laboratory networking and referrals. Based on these results, this initiative will be extended to all areas of the nation. The FLC has assembled a set of technical specialists who have volunteered to strengthen their network of contacts in the Laboratories in their specific technical areas. It has sparked the formation of a University Common Interest Group to increase cooperation and contacts between universities and federal laboratories nationwide; this model will be duplicated soon in groups with small-business and large-business emphasis. Cooperation between government Laboratories and other organizations can require an investment of time and manpower in agreement development and in determining acceptable models for cooperation; the FLC has demonstrated a significant role in transferring new cooperation methods and models among the Federal Laboratories. The FLC took the lead in establishing an Agency Liaison Group, the only inter-Agency forum on technology transfer policy and practice.

The discussion on this issue has provided a picture of some success and greater future promise. We believe that the FLC's accomplishments in stronger technology transfer will increasingly contribute to the Laboratories' broad ranges of mission activities, always provided as a service to the Laboratories.

CHANGES IN LABORATORY MISSIONS

Every effective organization has a specific, clear mission that is understood by its members even if it has not been articulated formally. This primary mission should pervade the entire organization and have a strong influence over the personality, or culture, of the organization. To ensure that the missions remain strong, they should be reviewed at least every five years.

If a Laboratory's mission changes, whether by broadening, contracting, or changing direction, a deliberate effort should be made to articulate the new mission to the entire organization. The alternative is to have the Laboratory's technical programs begin lose an important element of their vitality because they are not allied to a current mission. Worse yet, individual morale may be affected irreparably.

An alternative is to close a federal laboratory when its mission has been completed. The very possibility that this may happen can have a devastating affect on the staff even when closure is highly unlikely. Thus, long-range institutional planning for change and rapid, decisive action by Agencies in these circumstances are important if the facility is to be kept open and the vitality of its staff maintained.

A related issue is the relative roles of secondary missions such as technology transfer. To avoid compromising the impact of the pri-

mary mission, other important goals should each be the major responsibility of a member of the Laboratory's leadership. These goals can then be addressed properly, and wherever possible contribute to the Laboratory's primary mission.

ROLES OF THE LABORATORIES IN THE RESEARCH COMMUNITY

I believe that one of this nation's greatest strengths in science and technology is the variety of its R&D institutions. This allows these institutions to fit the needs and predilections of the scientists and engineers, rather than leaving our human resources with no choice of working situations. The Laboratories' roles, as contrasted with both universities and industry, reflect very different roles and opportunities for both the individuals and the Laboratories. Some of these special characteristics are:

o They often bridge the gap between basic research in the universities, and product development in industry. Development and preservation of a major technology base of expertise and facilities is a strong factor in this role.

o They can accept long-term assignments for programs or projects. Because government-sponsored work is their only source of support, these long-term programs can attract and retain top-quality technical staff.

o They can perform basic research without necessarily having an allied teaching responsibility.

o They can develop and maintain major experimental facilities and make them accessible to other users.

o Because of their government support, all unclassified results are published and they have a responsibility to the public to assure full availability of these results for commercial applications.

o The staff can have the flexibility to change technical fields and remain in the same organization; this also permits the Laboratories to develop new programs rapidly.

o Multidisciplinary and team research are more easily developed than in other sectors of the research community.

MEASURING THE PAYOFF OF SCIENCE:

This is a very difficult task. We would expect it to be much easier to quantify, for example, the results of direct technology transfer from a Laboratory to an industrial firm. The experience at Sandia Laboratories has shown, however, that the fact of a transfer can be documented; its economic value cannot, because most companies are unwilling to disclose sales or profit figures based on federal technology. Some of the Federal Laboratories have considered sponsoring such studies, but have generally conculuded that the available funds are better spent on increasing the accessibility of their technology to the private and public sectors. Even if the direct economic impact is measured, the social value of innovation is difficult to quantify; that is, the intrinsic value of a new technology may exceed the consumer's cost. Impaacts on national security are equally difficult to quantify.

One possible approach, neither comprehensive nor anecdotal, could be to ask an organization such as the Office of Science and Technology Policy to organize a study focused on a small number of research institutions and fields of science to provide an indication of the payoff.

Perphaps a more pressing issue should be to exploit opportunities to increase the payoff of science. Hearings last spring before the Subcommittee on Science, Research and technology explored the problems and potential in strengthening the economic payoff of Federal Laboratory research and technology. Those hearings indicated a significant opportunity to increase this payoff through stronger efforts at these Laboratories, involving decentralized authority but nationwide networking and cooperation.

TECHNOLOGY TRANSFER - - A BRIDGE THAT STRENGTHENS SCIENCE:

Some in the science community think of technology transfer and applications as a one-way street. In fact, the practical results of science do feed back both directly and indirectly to strenghten scientific pursuits and Laboratory missions.

Technology transfer inherently involves technical cooperation at a personal level. This cooperation can not only move technology to the public but also strengthens the originating organization. For example, cooperation with the industrial community provided major benefits in the design and construction of the Nova laser facility at the Lawrence Livermore National Laboratory. On a smaller scale, much of basic research is motivated by intriguing practical problems or oportunities, indicating the value of cooperation between researchers and technologists. Another direct benefit is improved research instrumentation that follows from commerical development of other research results.

The public's perception of the scientific community certainly influences through the political process the financial support for research. Dedicated efforts may be needed to assure the public that

the science community is a fully contributing institutional citizen--that it provides tangible value whenever it can, rather than isolating itself on a pedestal.

As addressed earlier in the Task Force's series of hearings, the continual availability of new scientific talent is crucial to the future of science. With all of our nation's social upheavals of the last 40 years, one clear result is the stronger social consciousness of many of the young. Their standards for self-satisfaction in a challenging profession are therefore broader than those for earlier generations. One result has been that many excellent science and engineering students have chosen to pursue short-term riches in the entrepreneurial private sector. At the same time, the pool of good students is expanding as artificial barriers to science careers for women and minorities have crumbled. In this atmosphere, I believe that careers in basic and applied research will be more attractive as the "connection" of science to society becomes stronger-- as the results of research become fully pragmatically available for commerical use to society's benefit; and as specific technical needs in the public and private sectors provide greater relevance to basic research endeavors. This potential for broadened satisfaction and opportunity is not limited to new scientists. It can be a constant source of renewal and motivation for science and engineering professionals at all stages of their careers.

A SUGGESTED INITIATIVE TO STRENGTHEN AMERICAN SCIENCE

Any major change in the relationships or aims of of the U.S. science community could occur only slowly, due both to individual and institutional attitudes and traditions. However, the nation's need for rapid industrial innovation, part of which is driven by the coupling of research to application, has not been greater since the end of World War II. New directions or emphases in this area cannot realistically be expected to solve the problems of budget deficits or balance of trade. But the scientific community can contribute significantly more then it does today, if it is open to a reaffirmation of its substantive role in society.

Though the efforts of the President's Science Advisor and other leaders in the Administration, the Congress and the techinical community, the issues of financial support and areas of emphasis are being addressed actively. What remains to be accomplished is an effective, grass-roots effort to couple science to applications with particular regard to the Federal Laboratories.

I was pleased to present a more detailed exposition on this subject to a hearing of the Science Research and Technology Subcommittee on May 22, 1985. The main points are summarized below:

o Stronger coupling of science to applications stregthens science through: institutional and individual respect that follows from substantive contributions to the nation's economy and security; an enhanced lure of science for talented students; greater opportunities for researchers' professional satisfaction; and the increased commercial availability of state-of-the-art instrumentation.

o The coupling of research to applications should be an integral part of each R&D institution's mission; depending on the institution, it may be a primary or a secondary mission. In any case, it should be recognized and accepted by the leadership and technical staff of each institution.

o There should be a clear national mandate and awareness of this strengthened coupling. The mandate will provide a clear signal to the research institutions; a greater awareness is needed in all sectors and sizes of business and industry so that they will seek their share of the bounties of science.

o In at least this area of endeavor, the authority and responsibility to engage in institutional cooperation and technology transfer should be decentralized at least to the individual institution. This is important because the recognition of potential innovation most often occurs at the working level and can be nurtured only at that level.

o Wherever possible, new or strengthed coupling of science to technology, therefore institution to institution, should be driven by the private sector: by large businesses, small businesses, trade associations, as well as by those state and local governments seeking greater economic development opportunities.

o In return, the research institutions should be properly accessible to these requests for cooperation. Non-government institutions will handle this increased expectation in their own ways. Within government facilities, grass-roots networking for both technical cooperation and for technology trnasfer should be strengthened.

ATTACHMENT

THE FEDERAL LABORATORY CONSORTIUM FOR TECHNOLOGY TRANSFER (FLC)

The FLC is a partnership of over 325 federal research and development laboratories and centers. Members are responsible for 85% of all federal laboratory research and development. Its goal is to provide the environment, the operational structure and the transfer mechanisms to support the fullest domestic use of unclassified federal technology. The Consortium's role is to assist its member laboratories in:

o Development of effective technology transfer methods and mechanisms;

o Transfer of federally developed technology to domestic public and private organizations;

o Application of federal talent, where appropriate, to domestic public and private needs;

o Establishment of networks with the rest of the technical community to refer requests or engage in cooperative efforts.

The FLC provides the only interagency, interlaboratory forum on technology transfer, and therefore facilitates significant cooperation among these institutions. Important results include: training of individuals newly assigned to technology transfer; the transfer of new technology transfer or cooperative mechanisms among the laboratories; and increased effectiveness and efficiency of each laboratory's transfer program through national outreach activities and efficient brokerage of technology needs and opportunities. Particularly as laboratories begin new or expanded efforts in technology transfer, this interpersonal network of experienced individuals has been a valuable resource for these laboratories in developing programs that

are both effective and complementary to their organizational cultures and missions. This cooperation has also proven directly valuable to the laboratories' missions through interlaboratory cooperation and laboratory-laboratory technology transfer.

The FLC is organized into six regional groups, each with a designated Regional Coordinator. These Coordinators form the FLC's operational backbone by serving both as (a) primary referral points in the network, brokering requests from their regions to the appropriate laboratories; and (b) organizers of special regional projects and efforts to market the availability of technology transfer to industry, state and local governments and universities in their areas. The FLC is governed by its member laboratories' appointed representatives through an elected Executive Committee; it has an advisory committee drawn from representatives of users. It holds national meetings semiannually as a forum for formal and informal exchange of information among member laboratories' representatives, and representatives from state and local government, universities, industry and Congress.

Networking

Because it represents a large resource of federal laboratories, the FLC can establish relationships with many organizations and groups representing potential users of laboratory technology.

Memoranda of Understanding - Several formal Memoranda of Understanding have been generated between the FLC and entities that share its interest in technology transfer. Existing agreements are with: Training Resources and Data Exchange; the Department of Commerce; US Conference of Mayors; Public Technology, Inc.; Florida Small Business Development Centers (and the Southeast Region, FLC); NASA Industrial Applications Center (and Farwest Region, FLC).

For the several states and areas without major federal laboratories, the FLC network can provide a unique opportunity to make federal technology and assistance available through the FLC regional coordinators. Two examples of enhanced interactions with such states have resulted from holding FLC-sponsored meetings: As a result of an FLC semiannual meeting in 1983 in Biloxi, numerous contacts and transfers were made between laboratories across the country and state agencies in Mississippi. At this FLC meeting, the representative from the Army Aviation Systems Command in St. Louis met a university professor who is now the science advisor to the Governor of Missouri. As a result of this contact, this representative will participate in an economic development conference sponsored by the Governor's office.

Because federal technology transfer is very resource limited, this mechanism has not been extended to all such states and locales. Special efforts by out-of-state laboratories have been made, for example, with Missouri, Oklahoma, Texas, Oregon, Mississippi, Hawaii, Arizona and Nevada.

COMET Electronic Mail System - Sandia National Laboratories have provided access to use their COMET Electronic Mail System to the FLC Executive Committee and representatives in the Sandia-coordinated Mid-Continent Region. It is used to circulate requests for information and assistance from FLC clients to the six regions via the Regional Coordinators.

One example illustrates its utility. The ORTA at Argonne National Laboratory relayed a request for information on electroluminescent signs to regional coordinators via COMET. Ninety minutes later, the ORTA at the National Bureau of Standards had relayed the request to a local expert who telephoned the requestor in Minnesota that day.

Examples of Networking Results - The Naval Underwater Systems Center heard about a computer software learning program developed at the Navy Personnel R&D Center. The program was created to teach vocabulary and literal comprehension specifically for Navy terminology and technical reading, but can be used to enhance those skills in any content area. NUSC decided to test it in a local school system for which their volunteer service was helping to develop a computer curriculum and computer requirements design. A workshop at NUSC, given by the NPRDC developer of the program, was attended by the Army Human Engineering Laboratory representative and he is now experimenting with it for a Reading Skill Improvement Program for the National Commission on Libraries and Information Science and the Baltimore County Public School System. To that end, a workshop was held at Harry Diamond Laboratory to train volunteer teachers to use the program.

Harry Diamond Laboratory had contact with Montgomery County, Maryland through its volunteer effort. A problem was identified in public works. The county needed information on waterproofing older (historic) brick buildings, and was especially interested in polymer coatings. HDL arranged for: a) advice from National Bureau of Standards on protection of brick buildings and b) evaluation reports on polymer coatings from the Army Corps of Engineers Waterways Experiment Station, Vicksburg, Mississippi.

A volunteer effort to provide an energy assessment for the East Lyme (CT) High School had direct benefit to a newly purchased industrial plant in Cambridge, Ohio: A request for assistance from a local assistance group, TRACES, to the Wright-Patterson Air Force Base was networked to the Naval Underwater Systems Center, which provided contacts on the project at East Lyme.

The Naval Air Development Center, PENNTAP and the FLC cooperated in transferring the Navy Preventive Maintenance Program to local governments through workshops and other assistance.

Through the FLC, the Naval Air Development Center (NADC) compiled information from three other agencies' laboratories on waste management, disposal and incineration for energy production. NADC is working with a consortium of townships in Pennsylvania to demonstrate and transfer this technology.

Development and Replication of Transfer Methods

Developing a technology transfer project within a laboratory can be time-consuming in addressing all operational and policy issues. The FLC assists both in developing transfer methods and in documenting successful approaches and transferring them to other laboratories.

Technical Volunteer Services - FLC member laboratories such as the Naval Underwater Systems Center (NUSC), along with several other public and private organizations, have taken the lead in establishing Technical Volunteer Services, available to communities surrounding their laboratories.

The FLC, with support from the Departments of the Army and Navy, the Administration on Aging, and individual laboratories, has been the vehicle for providing information, encouragement, training and assistance in establishing a TVS in all interested laboratories.

The FLC holds informational and training sessions on the intricacies of establishing volunteer services at its semiannual meetings. The FLC provides the forum for exchange of information and experiences, as well as the sharing of training aids among the laboratories.

The extension of this concept to other laboratories through the FLC has resulted in nine new programs in the past two and a half years.

Technical volunteers from the Naval Underwater Systems Center are working on a variety of aids for the physically handicapped. A task force of employees from NUSC's New London Laboratory are adapting toys and mobility vehicles for young (eighteen months to three years) cerebral palsy victims. The ability to use the adapted toys allows the children to gain some of the learning experiences that benefit unimpaired children. Members of NUSC's Newport Laboratory staff have developed a computer software program and adapted peripheral devices to assist young adults with cerebral palsy in improving their fine and gross motor control. These volunteer efforts have provided custom computerized communications systems to over 20 profoundly disabled individuals.

Expertise Data Base - The FLC, in cooperation with the Naval Material Command, supported development of a Technology Transfer Data Base at the Naval Weapons Center. Within the laboratory, it is used to locate individual technical experts for both mission requirements and for response to technology transfer inquiries. Although this detailed information is available only within the laboratory, for security and other reasons, a summary data base will be made available to other laboratories as a resource base for technology transfer referrals. Ultimately, through the FLC, it could be an important resource for all federal laboratories' internal operations, other mission needs, and technology transfer.

Technology Transfer Program Planning - The US Forest Service has developed a technology transfer program planning process to ensure rapid transfer of its developments in each program. Information on this process has been transferred to other laboratories through the FLC for their use.

Federal Laboratories Resource Directory - The FLC has taken the lead in proposing an interagency effort to develop a directory of federal laboratories, their major program areas and key capabilities.

The directory is intended to be an automated data base with inputs from the participating agencies. Two categories of applications are envisioned: information dissemination and laboratory management. A committee of FLC, Agency and CUFT representatives is working on locating a funding source and agreeing on specifications.

Marketing

Developing interest in potential users of federal technology, and making the links between the source and user of a technology are formidable tasks. These are assisted by the FLC through nationwide outreach activities (brochures, exhibits, articles), and the networking functions described earlier.

FLC-Industry Workshops - One need in effective networking is to provoke efficient communication between disparate groups. In cooperation with Technology Transfer Conferences, Inc., three laboratory-industry workshops have been held. Each workshop gives exposure of 10 laboratories to 30 major companies. Most laboratories report follow-up interactions based on these workshops, which are especially useful to smaller laboratories that are not known well by industry. Two such

workshops focusing on new materials and processes and agricultural and biotechnology were held in Philadelphia earlier this month, attracting substantial interest of both industry and the Federal Laboratories.

FLC-University Common-Interest Group - The FLC recently established a steering committee of individuals representing universities from five states to develop an FLC-University Common Interest Group. It will work to develop a national network of cooperation within which universities and federal facilities can cooperate in technology transfer; it will also strengthen FLC cooperation with universities through existing university-based organizations, such as the National Association of Management and Technical Assistance Centers and the National Productivity Network.

This is an extension of efforts in the FLC's Far West Region members in developing cooperation with the California State University campuses and the community colleges in California to develop a technical assistance network analogous to the Ohio Technology Transfer Organization.

Similar Common-Interest Groups will soon be formed with small business and large business.

Recognition-

Awards for excellence in technology transfer were established in 1984 to recognize laboratory employees who have been responsible for important transfers, but for whom technology transfer is not a major job responsibility. These and awards for FLC representatives and others help provide recognition and incentives for effective technology transfer.

Training

Through the FLC, both formal and informal training assists individuals new to technology transfer or those interested in new methodologies. About 25 new laboratory representatives receive orientation at each FLC semiannual meeting. Special training sessions onestablishment of volunteer programs have been presented. Sessions have been held at FLC meetings to introduce such subjects as trade association interactions, patents, issues in militarily critical technology, the needs of the aging, university interactions, state and local economic development, and technology transfer between federal R&D organizations.

The FLC's network also provides valuable person-to-person advice both to assist new technology transfer professionals in their new programs and to assist each other with ideas, perspectives and problem-solving in specific technology transfers.

Mission Benefits

Effective technology transfer professionals are aware of the technology, expertise and needs within their own laboratories. Through the FLC's forums and network, there are opportunities for laboratory-to-laboratory transfer and cooperation for direct mission purposes. In addition, in many technology transfer situations, particularly with industry, there is a two-way transfer that enhances the labortory's technology base for mission work.

EPA Region III Office (Pniladelphia) working through the FLC, surveyed technical resources that could be used in emergency hazardous/toxic waste problems. As a result of this survey, EPA was able to utilize special equipment developed at the Naval Explosive Ordnance Development Center, Indianhead, Maryland to locate a large group of buried barrels of hazardous waste at a site that became designated for Superfund activities.

Other Support Activities

FLC/Agency Liaison Group - In 1983, the FLC organized an Agency Liaison Group. This group has become a regular interagency forum on technology transfer issues, policies and methods. It also provides the FLC with input from its member laboratories' parent agencies on improving its services.

Federal Laboratory Directory 1982 - FLC cooperated with National Bureau of Standards' ORTA, in the preparation of the directory, NBS Special Publication 646 issued in 1983. It contains various summary data and an information sheet on each laboratory.

NBS has disseminated 3,000 copies. Recipients were all federal laboratories, 700 industrial organizations, policymakers in the Agencies and Congress, and repository libraries. An updated edition is in progress.

Mr. FUQUA. Thank you, Dr. Stark.
Dr. Hess, we will hear from you at this time.
[A biographical sketch of Dr. Hess follows:]

DR. WILMOT N. HESS

Title: Director, National Center for Atmospheric Research, Boulder, CO.

Education: B.S., Electrical Engineering, Columbia University, 1946, M.A., Physics, Oberlin College, 1949, Ph.D., Physics, University of California At Berkeley, 1954.

Honors, Offices an Societies: 1965—Arthur S. Fleming Award for one of the ten outstanding young men in the Federal Service, 1969—AIAA G. Edward Pendray Award, 1969—NASA Group Achievement Award, 1970—Honorary Degree, Doctor of Science, Oberlin College, Ohio, 1971—ASTM Thomas A. Marshall, Jr. Distinguished Lecturer on Research.

Past Associate Editor of *Journal of Geophysical Research, Journal of Atmospheric Sciences, Review of Geophysics, AIAA Journal, Moon and Space Science Reviews.*

1970–1976—Professor Adjoint, Department of Astro-Geophysics, University of Colorado, 1976—Elected to National Academy of Engineering, 1978—NOAA $1,000 Award for Special Achievement, Fellow, American Geophysical Union, Fellow, American Physical Society, Fellow, American Meteorological Society, and Fellow, American Association for Advancement of Science.

Technical Papers: Author of 87 scientific papers; author and/or editor of six books or special reports.

Experience: 1954–1959—Staff Member, University of California, Lawrence Radiation Laboratory, Berkeley and Livermore, CA.

1959–1961—Leader, Plowshare Division, University of California Radiation Laboratory, Livermore, California. Dr. Hess directed a division doing studies on industrial uses of nuclear explosives for building harbors and canals, recovering energy from underground explosions, producing oil from oil shale in situ, and other projects.

1961–1967—Chief, Laboratory for Theoretical Studies, NASA Goddard Space Flight Center, Greenbelt, Maryland. Dr. Hess directed a division of astronomers, plasma physicists, geologists, atomic physicists and geodesists doing theoretical studies on a wide variety of space science problems. He carried out a personal research program aimed at understanding the origin and characteristics of the Van Allen radiation belt.

1967–1969—Director of Science and Applications, NASA Manned Spacecraft Center, Houston, Texas. Dr. Hess planned and conducted continued programs of investigations in the areas of earth and lunar science; provided environmental data required to support spacecraft and mission design by planning and conducting programs involving the application of space systems and operational capability to the analysis and evaluation of the earth's resources; planned and conducted continuing programs of investigation in the area of meteorology with manned spacecraft; conceived, developed and integrated experimental instrumentation and equipment for use in the scientific and applications program; supported principal investigators in the development, integration, and conduct of experiments; planned and operated the Lunar Receiving Laboratory and other facilities required in support of programs; supported astronaut training in the areas of science and the conduct and operation of experiments; and provided space environment data and operational support of experiments during manned space flights.

1969–1980—Director, Environmental Research Laboratories, National Oceanic and Atmospheric Administration, Boulder, Colorado. Dr. Hess directed the activities of 11 research laboratories and a flight facility, employing about 1,400 people. These laboratories perform the major portion of the research in NOAA and work closely with the National Weather Service and the National Ocean Survey to bring the results of research programs into operational programs. The laboratories work mainly in the disciplines of meteorology, oceanography, geophysics, aeronomy, and space sciences.

For more than one year (1977–1978), Dr. Hess was the acting general manager of NOAA, having resources of $800 million and 13,000 people. In this capacity, he was responsible for many of the day-to-day decisions to keep the organization moving, especially those dealing with resources allocations, program planning and budgeting, and transactions between the various line components.

1980–Present—Director, National Center for Atmospheric Research, Boulder, Colorado.

STATEMENT OF DR. WILMOT N. HESS, DIRECTOR, NATIONAL CENTER FOR ATMOSPHERIC RESEARCH, BOULDER, CO

Dr. HESS. Thank you, Mr. Chairman, for inviting me to testify at this hearing on science in the mission agencies and Federal laboratories.

With your permission, I would like to submit my testimony for the record and give a short summary of it.

Mr. FUQUA. Yes. We will make it part of the record.

Dr. HESS. Thank you.

I have worked as the director of several Government civil service laboratories in NASA and in NOAA. I have also worked as the director of contractor laboratories. I am now at the National Center for Atmospheric Research which is vaguely a contractor laboratory but has various differences from the standard contractor laboratory.

I have a certain amount of perspective in this business seeing problems that exist for the operation of Government laboratories. I would like to tell you my personal views on some of these problems.

First, what does it take to make a good research laboratory? I would suggest the following set of conditions. First, you have to have an interesting research program that provides a challenge for a scientist working at that institution. This was a subject Mr. Ritter was talking about earlier. Does the organization or agency have a mission which provides a cleanly defined program that is exciting to the scientist working there? Then, you have to have a group of stimulating scientists, a large enough group, so that one can knock ideas around inside the group so that there is somebody to talk to about the things that you are working on that you consider a peer, a certain critical mass, then.

Then, you need a long-term, stable program. The vagaries of Federal funding make that difficult in certain research laboratories. Not only does it need to be long term, and by that I mean more than 3 years but 5 or 10 years in length, but it has to be in some way insulated from the political process so that the laboratory is allowed to operate as a research laboratory without having to contend with political pressures that move it in directions which are not those natural for a research organization.

You need local planning of the research program. That should be done inside guidelines set up by the agency, the sponsoring organization, that says this is the field of work you should work in, here are the problems we have as an agency. Inside that set of guidelines, the local organization should design its research program.

You have to have competitive salaries in order to attract and retain key scientific personnel.

I would submit that is a list of conditions that you must have to make a good research laboratory. I would say that almost all of those are violated when you look at the Federal system and try to see if it is possible to make a good research laboratory, to have a good research laboratory, inside the Federal GO–GO, Government-owned, Government-operated, laboratory system.

The first problem I would suggest is a serious one is the personnel system. By that I mean civil service and the related Senior Ex-

ecutive Service which is not competitive in salaries. The salaries that you are allowed to pay to a key scientist inside civil service are at least 30 percent, maybe 50 percent, below salaries that you ought to be allowed to pay if you are going to be able to retain key scientists in your organization.

The civil service system does not motivate a good employee. The system of rewards is almost completely lacking for a system that you would like to have in place to tell a person who is doing good work he is doing good work and to show it by giving him a bonus, by some other award that allows the individual to understand he is performing especially well.

The system of bonuses that was early promised in the SES system has turned out to not work at all. There are so few of them that they do not constitute seriously a motivation for a person working inside SES.

The civil service system also does not allow the manager or director of a laboratory to discipline a poor employee. It is almost impossible to withhold an in-grade promotion. It is very difficult to fire a nonproductive employee.

If you want to have a bad morale system, develop a system where poor employees are put in the same environment with good employees and there is no difference in the way management treats those two groups. That guarantees bad morale.

The personnel ceiling system imposed by Government is a nuisance or worse when looked at from the management of a laboratory. The fundamental control you should put on a research laboratory in the way of resources is a budget. Given the budget, you should try to make sure that that money is used properly to carry out the purposes that the laboratory has been set up for best, but don't put any artificial impediments in the way of the laboratory. Personnel ceilings, wage-bulge arrangements, travel ceilings, any secondary constraints on the way that the money is spent will almost automatically mean it is spent less efficiently and there is waste of money.

Inside the civil service system, there is called for an annual work plan. That work plan is essentially useless and a waste of time for people in research laboratories. You can't lay out a work plan that thoughtfully analyzes what a research scientist is going to be doing the next year.

You can suggest directions of work, but in saying what he should do and what he should accomplish over that period of time is essentially completely opposite to the concept of the word research. I would suggest that the whole concept of work plans should be done away with inside research laboratories.

Aside from that, I guess the civil service system works well. [Laughter.]

The recommendation that comes out of this is the same as the recommendation coming out of the Packard Committee, that there should be put in place a personnel system outside civil service like that recommended by the Packard Report for the operation of Government laboratories. I don't mean to say that the Government laboratories should be put into the private sector and made non-Government. I don't think that is probably the right solution.

But there should be a different personnel system put in place and that different personnel system should have a separate mechanism for setting salaries to make those salaries competitive with the outside world, with the peer group that you are interacting with outside, and the personnel system should have proper motivation built into it and proper disciplinary action built into it. You should be able to fire a nonproductive research scientist. You should be able to fire a laboratory director who is not doing his job well.

The second problem I would put to you is the matter of long-term stability. I think it is necessary to get away from the matter of having 10 or 20 percent up and down in budgets on a yearly basis for any research laboratory. That kind of instability shows in the staff and it means you will not retain your best people if they don't feel that there is a program that they can see through.

A typical program for a research scientist to accomplish something significant will take him 3 years, maybe 5 years. As a team effort, it might take 10 years to develop a large piece of equipment, a large program to go on a super computer. If it looks as if he is only going to be allowed 1 or 2 years because of the vagaries of funding, you are unlikely to retain that person.

I would suggest you ought to have at least 3-year funding and that this ought to be on some kind of a rolling basis where it is renewed before the end of the third year so that the continuity is then in place rather than at jeopardy at the end of the third year. You should build inflation into that 3-year contract so that the program is not going down hill as it moves forward.

Second, as a matter of long-term stability, it is necessary to insulate the laboratory from the political process. Now, a way to do that is to put at least one layer of management in between the laboratory and the political officers of the agency. That means it is harder for the political problems to be passed down. You tend to sort them out as the laboratory director and his boss do their jobs.

The next problem is the quality of research. It is clear that there are certain research laboratories attached to the Federal establishment that aren't as good as some other research laboratories. It is also clear that there are some world-class research laboratories in the Federal system, and we should all be proud of that. I would submit to you that it would be very difficult today to start a laboratory and grow it to world class in a decade with all the impediments in the system.

How do you guarantee quality of research? How does the sponsoring agency find that it has a good product and its people are doing good research?

The suggestion that Mr. Packard put forward of having peer review is clearly the way to do this. Have an external organization come in and review for quality. We have this system in place at NCAR. I have used it in the past at NOAA.

The National Academy of Sciences does this kind of peer review for several agencies of Government and does it well. They put together a peer review committee made up of notables of the field that is to be reviewed, representatives of universities, of Government laboratories, of industry, and that team will come in and review both the work of the last 2 or 3 years and the plans for the

short-term future. In that way, you get a feeling that the work carried out is of high quality.

The research program we have in place carries out that review down to each Ph.D. scientist's work on a 3-year basis. I feel that is very satisfactory. It provides us with a completely clear look at what is going on inside our laboratory as viewed from outside, how good it is, where weak spots are.

I think that review should be carried out both for the director of the laboratory and for the sponsoring agency.

One other problem, the matter of procurement. Inside the Federal system of civil service laboratories, procurement using the Federal procurement regulations is a very difficult business. I have recently seen an example of this where an agency I am familiar with got the money in their budget in 1980 to procure, not a supercomputer, but a medium-sized computer, and they didn't get it in place on the floor until 1985, 5 years later. At least half of that time was strictly the result of the Federal procurement regulations.

In our laboratory and laboratories outside the Federal system that don't have to use those procurement regulations, I think we do an honest, honorable job of procurement. It is audited regularly. We don't have the laborious scheme you have to go through inside those regulations. I would submit you ought to do something to try to get rid of those, not have that impediment in front of the laboratory director.

In summing up, then, I agree very completely with the findings and the recommendations of the Packard Report. I think that the views that are put forward there on making an independent personnel system, making sure that you have quality peer review are very important.

I have recently seen a copy of the newly introduced Federal Science and Technology Revitalization Act that your chairman put in. I support very strongly the objectives of this bill. I might have a few questions about particulars in it, but I think that goes a considerable distance to solve some of the concerns I have in the system although not all of them. That helps very much in the area of personnel in moving toward a system which would allow Federal Governments to work well. There still would be some other problems left over.

I thank you, Mr. Chairman.

[The prepared statement of Dr. Hess follows:]

TESTIMONY OF DR. WILMOT N. HESS
DIRECTOR, NATIONAL CENTER FOR ATMOSPHERIC RESEARCH*
BEFORE THE HOUSE OF REPRESENTATIVES SCIENCE & TECHNOLOGY COMMITTEE
TASK FORCE ON SCIENCE POLICY ON OCTOBER 22, 1985

Thank you, Mr. Chairman, for inviting me to testify at this hearing on "Science in the Mission Agencies and Federal Laboratories." I have worked at government Civil Service laboratories (government-owned government-operated laboratories) at NASA Goddard Space Flight Center and NASA Manned Spacecraft Center and NOAA Environmental Research Laboratories. I have also worked at contractor laboratories (government-owned contractor-operated laboratories) at the Lawrence Berkeley Laboratory and the Lawrence Livermore Laboratory and I am now at the NSF-sponsored National Center for Atmospheric Research.

Because of my background I have some strong feelings about the problems of developing and running a research laboratory, both as a government-operated Civil Service laboratory and as a contractor-operated laboratory. In mission agencies such as NOAA, NASA, DOE, EPA, there are substantial research programs, some of very high quality and some of medium quality. It is perhaps surprising that the general quality of the research programs is as good as it is given the constraints under which these agencies must operate.

First, let us look at what it takes to make a first-class laboratory and then look at several reasons why it is very hard to achieve this goal in government mission agency laboratories.

---

* sponsored by the National Science Foundation

What Makes a First Class Research Laboratory?

First, you must have an interesting research program. This, of course, depends upon the mission of the agencies involved. Many government organizations have program responsibilities in areas that involve them in the cutting edge of physics, chemistry, engineering, and/or environmental science. Let us assume the mission of the laboratories we are interested in is clearly enough stated and has a strong scientific component so that the reason for the existence of research laboratories in this agency is obvious and the general area of research work should be exciting and productive. What else is needed?

A second requirement is that there be a group of stimulating scientific colleagues to work on these problems. Few things will discourage a first-class scientist more than not having a scientific sounding board. You must have a critical mass of high quality research personnel to make a good lab function. This of course takes a period of time to develop.

A third requirement for a high quality laboratory is a long-term, stable research program. The program that changes objectives every two or three years, that moves with the political wind, and that does not allow a research team to seriously challenge important problems over the long-term will not prosper. Most significant research programs take several years to produce useful results. It is not surprising for a group of scientists developing a complicated numerical model of the atmosphere, for example, to work a decade or more in the development of a high quality product. This time scale is probably similar in many other disciplines.

Fourth, one needs local control of program planning. No strong research laboratory is centrally planned from a Washington headquarters office. Essentially all good research ideas percolate up from the working scientist to management, and management then has the job of sorting out the best ideas and sculpting the best programs of work on agency problems. Centralized planning as practiced in the Soviet Union does not produce good agricultural output or good factory production, and it certainly doesn't produce good research programs.

Fifth, a Director of a high quality research laboratory should almost always be a scientist or engineer who is familiar in detail with the work done in the field of research of the laboratory. Professional planners or business people generally do not do as well because they don't understand or have experience with the science involved, laboratory structures, or how to develop a research strategy.

And sixth, a strong research staff must be paid salaries that are competitive with the other parts of the research establishment with which they interact. If the principal source of recruiting for scientists is from universities, for example, then you must pay salaries that are competitive with that environment. If the recruiting arena is in private industry, you must pay that level of salary. If you don't, you won't keep your team together very long.

If the research laboratory has all of the above ingredients then you must give it time to produce important results. It takes a decade or more

to grow a world class research laboratory. There are world class laboratories in several of the mission agencies and they are laboratories that have been nurtured and supported for decades.

If these criteria accurately describe what it takes to make a good research laboratory, how easy is it then to develop and maintain a first class lab in a mission agency of the U.S. Government? There are enough hurdles put in the way of a government-run organization that it is not surprising there aren't more of them. What are these road blocks? And how can we overcome them?

Personnel System

The personnel system used by most government laboratories is the Civil Service System. This has many serious shortcomings. It is not run from the viewpoint of developing or maintaining a good research laboratory at all. I am not sure it works well for any component of government but it clearly works very badly for research scientists. Here are some of the things that are wrong with it.

1. Civil Service salaries are not competitive for good research scientists. They lag considerably behind salaries for senior university faculty and even farther behind salaries for senior research personnel in high tech industries. In the laboratory I direct, the National Center for Atmospheric Research, which is not Civil Service, we have trouble keeping our salaries competitive with universities, and sometimes lose key research scientists to university jobs paying considerably more than we can. Our salaries are higher than Civil Service salaries for most research positions,

so government laboratories will clearly have more trouble than we do. If you want to get, and hold, good research scientists you must pay competitive salaries.

2. The Civil Service salary system does almost nothing to motivate the employee. If a scientist does an outstanding job on some particular project, can his lab director reward him appropriately? The answer in many situations is no. The scientist's salary is embedded inside a system which is completely inflexible. It recognizes no differences between special scientific disciplines in high demand - for example, systems programmers, or research physicists with years of experience - from people with skills much more widely available.

When the senior executive service (SES) was started, it promised bonuses and awards to high performing individuals which would have been a considerable motivating factor. Now that the system has been in operation for some years, it has become apparent that there are so few of these awards available, even for the really deserving people, that they do not constitute a realistic motivation at all.

The Civil Service System also discourages a manager or lab director from trying to hold back a poorly performing employee. If a person is not performing well, his supervisor should be able to withhold an in-grade pay raise. Withholding an in-grade pay raise is now so difficult that they are essentially automatic. If an employee is really performing poorly and a supervisor thinks he ought to get rid of him after the probationary period is over, this takes a lot of doing. There must be an extensive period of collecting information to show the employee is not performing adequately.

Then there is a very lengthy review process including hearings before the Merit System Protection Board. This system is so onerous that a supervisor, rather than trying to use it, frequently decides to put the poorly-performing employee in a corner somewhere where he can do no harm and forget about him. This is bad for the morale of the entire organization and a waste of taxpayers' money.

3. Personnel ceilings and grade-bulge restrictions should not apply to research laboratories. The primary control on a research program should be the budget. Given a certain level of funding from the mission agency, the laboratory Director should have the freedom to decide how many people are needed to do the job and what the mix of junior and senior people should be. Any arbitrary limits on personnel simply mean the job will be done less well.

4. In the Civil Service System, each supervisor writes an annual work plan for each employee supervised, laying out what is expected of that employee during the next year. This is absolutely useless and wastes a lot of time for managers and scientists in research laboratories. It may be useful for people who are in repetitive tasks in manufacturing, but it is just waste motion in a research environment. It ought to be done away with.

As you can see, I feel strongly the Civil Service System is very bad for research laboratories. What can be done instead?

A separate scientific personnel system, independent of the present Civil Service System, should be set up for research laboratories. Such a system already exists in many laboratories operated by the private sector for the government. It also seems possible to have such a system inside a government-owned, government-operated laboratory. The Naval Weapons Center at China Lake has experimented with such a system and it seems to work. This personnel system should be under the control of the research laboratory with appropriate oversight by the sponsoring mission agency. It should set salaries competitively. It should provide motivation so the managers could reward good performance and get rid of poor performers. I know such a system will work because we use this system at our NCAR laboratory.

Long-Term Stability

How can we make a research laboratory have the appropriate stability to allow it to carry out a strong research program? One essential ingredient in this stability is that the budget of the laboratory not fluctuate violently. If you have a ten or twenty percent reduction in the budget of a lab for a couple of years, and then a ten or twenty percent increase, this kind of instability will cause serious problems with the senior research staff. They will be inclined to move somewhere else where the budgets ARE more stable. The way to achieve stability would be to have multi-year funding for research laboratories. If it takes three years or more to get substantial results from a research program, give the laboratory Director money for three years. Include enough in the second or third years to pay for inflationary increases. All of these funds should be no-year money so that they can be carried over into the next year. In this way you prevent the silly scramble to spend year-end funds, which is often a waste of public funds. Then at the end of the three-year period, carry out a review of the

laboratory and find out if the work carried out is of high quality and should be continued. If it is not, make appropriate changes. If it is deemed to be high quality, write another contract for funding the next three years. In this way the short-term fluctuations in funding could be done away with. The laboratory would still have the possibility of responding to new program directions which were not anticipated at the beginning of the three-year period by going back to the mission agency for incremental funding. But the base funding of the laboratory would be stable over the three-year period. The problem with the system now is that one-year funding with its inherent fluctuations often causes serious difficulties for the government laboratory where research programs require five years or more to come to maturity.

I think it would be a wise idea for Congress to move toward multi-year funding for all government agencies, but I think it is especially important for a research laboratory where stability is essential in order to carry out long-term programs.

A second ingredient in the long-term stability need has to do with insulation from the political processes in Washington. Basic research programs take years to produce meaningful output. To have the laboratory objectives or research program pushed around every year or so by some new political pressure will help to guarantee loss of productivity and waste of public funds. The organizational structure of a mission agency should have at least one layer of insulation between the Director of the research laboratory and the agency's political officers in Washington who must respond to these political pressures.

Procurement

Another factor affecting many research agencies concerns the extremely laborious and long procedures necessary to procure major equipment items for the research programs using federal procurement regulations. It now takes an average of two years from initiation of procurement until the laboratory has a medium-size computer in place. With such delays built into procurement, it is not surprising that some laboratories have trouble meeting deadlines. The procurement staff should work directly for the research laboratory and not for a central agency office in Washington. The procurement specialists should be familiar with scientific problems and the general program of research of the laboratory. One way to solve both the matter of insulation from the political process and the problems with federal procurement policy is by having the laboratory operate either by the private sector or in some other system not directly run by a federal agency and hence subject to politics, or to federal regulation affecting personnel and procurement procedures.

Peer Review and Peer Interaction to Assure the Quality of the Research Program

How can the mission agency make sure that it is getting the public's moneys' worth from a research laboratory? If the laboratory operates rather independently, as I have suggested, will it do the kind of research that will help carry out the agency's mission and will it be high quality research? There is a simple, straightforward way to make sure the program is appropriate to the agency's mission and it is of high quality: have an external review of the agency's program conducted by scientific peers every two or three years. The National Academy of Sciences (NAS/NRC) has carried

out this review process for a number of agencies in the past. It could be done by other independent scientific organizations, but the NAS does it well. The NAS puts together a review committee made up of highly qualified research scientists who have broad views of research and its relationship to the missions of the agency. They are recruited from universities, not-for-profit organizations, and industry, and represent a broad spectrum of the scientific thought in a specific research area, and produce an independent and insightful evaluation. Such a review committee will tell management if the research lab is not performing as well as they think it should be. I have been through these reviews carried out by NAS. They are tough, but they are fair and they are extremely useful to management. The management can decide whether part of the program or the personnel involved should be altered, and find out if first class work is being done or not. Some mission agencies do not use this external peer review process and in some cases it shows. The NOAA Environmental Research Laboratories used to have NAS reviews but they do not now. I think they should return to the old system.

Another extremely important characteristic of a good research laboratory is that its scientists interact with those working in its subject areas in other organizations such as universities. Most of the basic research work in the United States is done outside government laboratories, a large portion by universities. It is essential that a good laboratory keep in close contact with the strong research groups in its subject area. This means writing research papers published in the refereed journals. It means attending the research meetings of the appropriate national organizations in the field - the APS, ACS, AGU, etc. But above all, it

means working collaboratively with the leading scientists in the field. This means having university scientists spend sabbaticals at a government research laboratory. It means having post-doctoral fellows from all of the important universities spend a couple of years there also. These people bring in many new important ideas in research. Without this new blood coming from the universities, an organization tends to get intellectual "hardening of the arteries." The NAS review committee should look very hard at the collaborative research program being carried out by the mission agency laboratory. The more of this the better. Probably as much as ten percent or more of the budget of the research laboratory should go directly to sponsor these collaborative activities. The NAS peer review committee should comment on the quality and quantity of this collaborative effort.

Control by the Sponsoring Agency

The image of the productive government research laboratory that I have drawn is one with a good deal of independence. There is bottom-up planning; local control of personnel, salaries, and procurement; and outside review and interaction to assure the quality of the program.

Now then, how does the mission agency make sure that a mission laboratory is doing something useful for that agency?

1. The mission agency should set general objectives for the laboratory program. These objectives should be to help develop knowledge in particular areas or on particular broad problems, in order to help the agency carry out its mission. You wouldn't expect to find an EPA research laboratory working on cosmology or archaeology. You would expect it to work in broad areas of

the environmental sciences tailored in such a way that they will help the EPA set the mission standards for pollutants and other regulatory requirements necessary to carry out that agency's mission. These general objectives stated by the agency should be broad so that the laboratory Director has a reasonable amount of freedom to develop the specific program that implements the objectives.

2. The laboratory should set up the research program inside the general objectives as laid out by the agency and then tell the sponsoring agency what it plans to do in detail to help the agency's mission. The laboratory should write a program plan each year saying what work will be carried out during the following year for the agency. This is a control document. The agency should approve the plan if it is appropriate. The agency should not try to micro-manage the program.

3. The agency should accept the peer review by the NAS or an equivalent mechanism as the necessary oversight of the scientific program of the laboratory.

4. The agency should review the administration and management of the research laboratory once every two or three years. Inside the flexibility inherent in the system I have outlined, the agency could change the management, and alter the research program if necessary to produce first class work in appropriate areas.

This image of a research laboratory I have put forward works. I know it works because it is more or less the system we have at NCAR. There are a

few world class laboratories that operate under the Civil Service System such as the Wave Propagation Laboratory of NOAA. It is frankly surprising to me this is possible at all. I am convinced by experience that it is much easier to do high quality work inside the system I have described.

If the government really wants to do first class research in its mission agency laboratories, it has to change the rules and operate with a system that has much more flexibility and much more motivation built into it. I know it is possible to develop world class laboratories when you operate with these flexibilities. I believe it would be next to impossible to start a research laboratory now inside the current regulatory constraints on government laboratories and ever develop a world class organization.

Thank you for the opportunity to appear before the Science Policy Task Force. I would be delighted to answer any questions you may have for me.

Mr. FUQUA. Thank you very much, Dr. Hess.

I am going to have to excuse myself in a few minutes. We have a conference committee meeting this morning on an item called Gramm-Rudman that might have some impact on both of you.

I would like to address this to both of you. Getting back to the Packard Commission recommendation on the scientific personnel system—and I have introduced a bill to accomplish that—as an alternative to that, if we cannot get that bill through, would it be bad to convert all the Federal labs over to GOCO's? The two that you two come from do rather well as a GOCO—Government-owned, contractor operated. Would that be the worst thing in the world?

Dr. HESS. I think there are some things that would be practical problems with it. I am not sure that it is the worst thing in the world, but I would submit that if you took a laboratory that had been in existence a long period of time as a civil service laboratory and tried in a short time to convert it to a privately operated laboratory, you would present some problems for some of the employees in the lab who might have 18 years of civil service and are working up toward retirement. If you suddenly take them away from that system, you cause them a practical problem.

I don't think there is any particular reason why any one particular laboratory should not be converted to a privately operated laboratory if there is a gradual and reasonably long transition period. I would submit it is probably not proper to try to do all of them.

Mr. FUQUA. Dr. Stark?

Dr. STARK. Aside from the issue of the retirement issues, my personal feeling is that the GOCO—Government-owned, contractor-operated, laboratories—certainly have the degree of independence and decentralization of authority and responsibility that I personally feel makes for a much stronger institution than is possible with many of the federally operated laboratories.

Mr. FUQUA. What discretionary funds do you have in the Los Alamos or the members of your group and also NCAR, as we discussed with Dr. Packard, that you can do independent research with your scientists?

Dr. STARK. Within Los Alamos, we have a program called institutional supporting research that is considered a part of the laboratory's budget. It is part of the laboratory overhead item. An internal committee decides on a year-to-year basis which projects proposed by individuals within the laboratory to support under that program. So, it is not so much a matter of giving individuals 5 or 10 percent of the time to do their own thing, but rather a matter of making it available to all to propose to spend 6 months or 1 year or more full-time doing their own thing if they can pass an internal peer review process.

Dr. HESS. A relatively small portion of our research money is flexible, but I think the answer to the question is more or less the same answer here.

Inside our research program, our scientists are allowed a reasonable degree of flexibility. We like to see scientists working on large programs, developing a big new instrument, helping carry out a large field program, developing a big code for a supercomputer.

Also, we want that individual to be doing some research on his own.

I would submit that 10 percent is probably not enough. I think 25 percent is a more reasonable kind of a number. In our laboratory, that spectrum goes from 100 percent, in some cases, down to a small number, maybe as low as 10 or 20 percent.

When we look to promote a scientist, we look at what he has done in field programs, in developing instruments, and in writing scientific papers. We go out and ask for peer review from his peers in universities to write letters and say how well this individual has performed. If he hasn't written some scientific papers, he has some problem getting that review accomplished well.

You have to have a mix in order to evaluate the individual well and also to keep the individual motivated.

Mr. FUQUA. When we have external review committees that come in and they tell us after the fact whether we have been doing good science or mediocre science, and the research is rather expensive and it has been going on probably for several years, how can we guard against waste while trying to reduce needless reporting and so forth?

Dr. HESS. I suppose a certain amount of waste cannot be guarded against in this kind of a system, but I would submit that that amount of waste is small compared to the amount of waste that you may get now inside the laboratories where you don't have this kind of a system in place.

If you review, postfact, say, for the last 3 years of work, you might find that there were some things that went on in that last 3 years you didn't like, in which case you would try to change them. In the absence of reviewing, you may have something that is going on that is not very good for 10 or 20 years.

I think that the postfact review will show those problems adequately and the amount of waste is small enough that you ought to be able to tolerate that.

Dr. STARK. My only addition would be, I think, that reporting to agencies or others should be done on a no more frequent than an annual basis. I have been familiar with laboratory programs requiring bimonthly reports to Washington by individuals who basically had to spend their full time writing reports before the advent of word processing systems made it easy to do so.

That is a very serious issue, and reporting after the fact, indeed, can bring out problems and there is far more efficiency in the few problems that are corrected after a year in review than in trying to micromanage and correct on a monthly or semiannual basis.

Mr. FUQUA. Thank you.

Mr. Ritter?

Mr. RITTER. Thank you, Mr. Chairman.

You mentioned some very substantial difficulties, Dr. Hess, on the personnel side. What about the facilities and equipment side? Where do we stand today vis-a-vis the competitive research arena compared to where we stood 10 years ago?

Dr. HESS. I think universities have a serious problem in the matter of research equipment. I am not familiar in detail with this, so I would say I have heard this secondhand from many colleagues who——

Mr. RITTER [acting chairman]. I am thinking about the labs. We have heard a great deal about the university problem, but what about the labs themselves?

Dr. HESS. Inside the Federal lab system, there has been a big step forward in the last year in the matter of providing supercomputing capability to the laboratories and the scientists related to laboratories. I would submit that that is probably in pretty good shape.

Inside the laboratories I am familiar with, there are serious needs for other kinds of equipment. At least in our laboratory, that is in direct competition with salaries for scientists, and you always have to compromise on this. You end up compromising in ways where you get good scientists, you get some equipment, you end up somewhere in the middle. There are clearly needs for new equipment in Federal labs.

Dr. STARK. I think I would say the needs for Federal laboratories are far less pressing or acute than the needs of universities in this area.

Mr. RITTER. The chairman mentioned trying to solve some of these personnel difficulties via the GOCO route. Is there a need for perhaps a legislative approach which would address not only the personnel difficulties but the idea of defining mission? Are we at a stage where the system has somewhat not kept up with the needs of the times in that there are such constraints on the national and Federal lab system that they are almost hamstrung to respond?

Dr. STARK. I don't know if there are any restrictions that are there intentionally, but I think the system has evolved in such a way that we are to some extent hamstrung. If we ask the question who is responsible for long-range strategic planning as to the types of research that ought to be carried out in the Federal laboratories, I would be hard pressed to find examples of where that is done very effectively from the standpoint that it is made very clear to the laboratories well in advance where they should be going.

That is a clear issue to me.

Mr. RITTER. Dr. Hess?

Dr. HESS. We are not a Federal laboratory in the normal definition of that phrase in Washington, and we are not hamstrung in that sense. We have a quite clearly defined mission which is to help universities carry out basic research. We work closely with the National Science Foundation which is our sponsoring agency in setting up programs to accomplish that, and we are very closely reviewed by university groups.

I don't think we have a problem with the mission or how we carry out the mission. I think we are reviewed and counseled at about the proper level. I can't answer for other Government labs.

Mr. RITTER. So, there seems to be some differences. The NSF-run laboratories, would you say, have better definition and less hamstringing?

Dr. HESS. In our case, that certainly is true. I don't know that I should generalize that, because I don't know enough about the other laboratories to say that.

Mr. RITTER. What about the Dole-Michael-Ritter-Shaw-Fuqua bill for some financial incentives within the system to participate in royalty sharing? Dr. Stark, could you comment first?

Dr. STARK. I am well familiar with that initiative and I personally support that very strongly from both standpoints that, No. 1, it provides a real opening for patents or other technology developed in the Federal laboratories to become pragmatically available to American industry where pragmatic availability may include the need for exclusive licensing which is otherwise difficult to obtain. From the standpoint of royalty sharing, my one concern would be that royalty or other income flowing back to a laboratory be made available to reward not only commercial innovation but also important mission related innovation and contributions by members of the technical staff.

Dr. HESS. I think the concept of royalty sharing is a very good one and should be pursued. I don't think practically for my laboratory it will amount to very much, because we do not get into situations which lead to the development of new systems where you are likely to make very much money.

Mr. RITTER. Gentlemen, thank you very much for your excellent testimony.

RECEIVED
DEC 2 1985
COMMITTEE ON SCIENCE
AND TECHNOLOGY

The Honorable
Don Fuqua
Committee on Science and Technology
2321 Rayburn House Office Bldg.
U.S. House of Representatives
Washington, DC 20515

Dear Representative Fuqua:

This is in response to your letter of October 24 requesting that I address specific questions for the record of the October 22 hearing of the Task Force on Science Policy. These responses reflect my personal thoughts on these subjects as garnered from interactions with individuals from a wide spectrum of federal laboratories through my role as chairman of the the Federal Laboratory Consortium (FLC). Several generalizations may not be applicable to all laboratories or agencies.

1. The costs of technology transfer and the laboratories' enthusiasm.

In most agencies, technology transfer is mandated as an overhead function of the larger laboratories. This approach has ensured that costs are minimal; thus the highest-value transfer opportunities are emphasized. The benefit-to-cost ratio is therefore high.

Positive attention was not generally given to government-industry cooperation and technology transfer in the 1970s. However, the passage of the Stevenson-Wydler Act in 1980, the continued congressional interest in its implementation, and more recent emphasis on international competitiveness of US industry have created a strong climate to which the laboratories are responding. Significant strengthening of technology transfer has been evident in the last four years and indications are this trend will continue.

2. Allocation of transfer resources.

The NASA Technology Utilization program has had the most resources available. There has been a smaller allocation of technology transfer resources at other federal laboratories. All such resources, including NASA's, sometime find the demand and opportunity for transfer outstripping available resources. On a laboratory-specific basis, consideration is given to increasing resource allocations based upon detailed analysis of incremental benefit and cost, applied with particular stringency in laboratories that support this activity from their overhead activities.

FLC CHAIRMAN
Los Alamos National Laboratory • MS F-685 • Los Alamos, NM 87545 • DR. EUGENE STARK • (505) 667-4960

The Honorable Don Fugua November 22, 1985

3. Laboratory functions and contribution to national goals.

The laboratories have few major functions that are not an integral part of their assigned missions. Some important functions within the missions include the maintenance and improvement of facilities, equipment, expertise, and technical vitality of the staff. Other functions are mandated by the government or are a consequence of their mission activities; these include use of unique capabilities to address other federal needs, the professional-society contributions by the staff, contributions to the educational system, and technology transfer.

Some laboratories strive to address "national goals," however, their mission activities must have first priority. Functions related to technolgy transfer and education may contribute, for example, to the generally-understood national needs in these areas.

The above observations are consistent with a trend by the laboratories toward an increased focus on their assigned missions.

4. Quality of Technical Personnel.

Until recent years, the federal laboratories had an excellent record of attracting and retaining high-quality technical talent, at least from the staff levels through middle management. The increasing difficulties of government-operated laboratories can be traced largely to salary differences with the private sector - an issue that has become critical.

5. Policy on Laboratory Establishment and Reorientation.

This policy area has not been a subject of discussions, either formal or informal, within the FLC. These are issues that must be considered carefully by each agency in its responsibility for stewardship of these major facilities and the substantial institutional expertise they maintain.

6. Roles of laboratories relative to universities and industry.

There is minimal duplication of work between the laboratories and other sources of R&D. The ultimate goal of each laboratory program requires a certain level of continuous in-house development that must be fed by applied research, which is often dependent on basic research. These requirements for continuity, independence, government-validated results, and goal-centered activity characterize the laboratories' roles.

An important step in strengthening American science and its results is the present trend toward institutional cooperation to mutual advantage. For example, the laboratories may offer greater educational and research opportunities for the universities, using government-owned facilities and equipment; program and research collaboration among these three sectors can strengthen their mutual respect and understanding, leading to strengthening of all the institutions and a better net return to society.

Sincerely,

Eugene Stark
FLC Chairman

RESPONSES TO QUESTIONS RE HESS TESTIMONY

1. What is the role of the National Science Foundation laboratories versus mission agency and private sector labs?

The NSF national laboratories were established to be extensions of university research capabilities, in order to advance the progress and the usefulness of university-based research and education. They carry out or assist programs primarily in basic research.

It has long been recognized that a strong economy and our national security depend on a strong infrastructure of basic research, and that the universities represent the deepest reservoir of talent in basic research. Futhermore, there is a very close tie between university-based research and the training of the next generation of basic scientists.

The purposes of mission agency and private sector laboratories are different. Mission agency labs are there to help the agency improve and modernize the performance of the agency's mission. Laboratories of private companies are directed toward the short or long-term profitability of the company.

There is frequently some healthy overlap between the work of NCAR scientists and their university collaborators and that of scientists in mission-agency laboratories, and sometimes there are joint projects shared by NCAR, universities, and the mission agencies. These activities promote progress in basic research and they help to move basic knowledge into use by the mission agencies.

2. What, besides the primary mission, are NCAR's functions? How are national goals as well as agency missions served?

NCAR has a dual mission:

- To plan and carry out research programs of highest quality on selected problems of national and international importance and scope.

- To identify, develop and make accessible selected research services and facilities of the outstanding quality required by the universities and NCAR for effective progress in atmospheric research.

NCAR's mission thus differs from the other NSF laboratories, which specialize only in providing powerful research tools, such as large telescopes, to the astronomical research community. In contrast, NCAR's mission is to work in concert with universities to bring about collaborative research programs that a single university cannot tackle alone. This means not only the provision of facilities but also scientific leadership in the identification, planning and execution of research activities of importance to the nation.

NCAR's facilities are so large, expensive, or complex that they could not easily be acquired or developed by a single university. We now have two CRAY-1 computers that are provided to NCAR and university researchers. This coming summer we will get a new CRAY X-MP 4800 computer to augment our computing capabilities for university work. Our computers presently serve roughly 1000 university users. We have four specially instrumented research aircraft that carry out research on severe storms, atmospheric chemistry, and studies of the surface of the ocean. We also have probably the world's best Doppler radar.

Our four aircraft, three Doppler radars, sixty automated meteorological ground stations and other specialized equipment are used nearly every year in large field experiments. We frequently take lead responsibility in organizing and managing field experiments and in preparing the data for use by investigators afterwards.

Another function of NCAR is education. Every summer we have one or more short courses for graduate students and young PhD's from universities in such subjects as atmospheric chemistry, advanced instrumentation, and how to use a CRAY computer. We have about twenty-five post doctoral fellows in residence at NCAR at all times. Each year, we have about twelve graduate students, jointly sponsored by NCAR and a university, working on thesis problems. We have roughly forty other long-term visitors (six months or more) carrying out special projects with our staff. A large reason for the existence of our research staff is to work jointly with university scientists.

In carrying out our NCAR research, we frequently get involved in national problems because we have capabilities which can be brought to bear on them. We are presently working on the development of an acid rain model for EPA. This is to be delivered to them next year. It will clearly be the best meteorological-chemical model that has ever been built anywhere. Specifically it will help to do the job of understanding and regulating the formation of acid rain.

We have worked for several years on problems of aviation safety, especially the phenomenon called downbursts. This down-flowing of cold air out of a cumulus cloud can pose a serious hazard to an aircraft when landing or taking off, as was recently learned in the Dallas airport

tragedy. We have studied the characteristics of downbursts, their occurrence, duration, and severity at the Denver Stapleton Airport. We are getting ready to do this at other sites and also to work with FAA on the development of a Doppler radar system to warn aircraft of the occurrence of downbursts.

We have worked on the problem of nuclear winter. Our Community Climate Model was the first one used to study in three dimensions the climatic effects of the soot cloud that could result from a nuclear war.

We work on national problems when we consider we have a special capability that can be brought to bear, and where we feel it is an appropri te extension of our overall program.

3. To what extent do Federal laboratories conduct research in-house that could just as well be performed at a university or a private research institution? How can we ensure that the Federal labs do not usurp the roles of these other institutions?

Laboratories of the mission agencies have special kinds of research programs to help improve the agency in the conduct of its mission. For example, the NOAA Environmental Research Laboratories developed Doppler radars which are now ready to be put into operation by the National Weather Service in their NEXRAD program. This kind of research which takes a decade or more and many people to carry it out is not appropriate for a university. However, there are research functions in mission agency laboratories that can be carried out by universities. An example of this is the pre-STORM program carried out last spring by NOAA-ERL, NCAR and about twelve universities. This joint project collected new data on how severe storms work, and is a good example of cooperation by the mission agencies and university researchers.

In certain other federal laboratories where the mission of the organization might not be as well defined (the Packard Report suggested some of the DOE laboratories might have this problem), there may be more confusion about the role of the laboratory and the role of university research. I cannot speak with firsthand knowledge about these situations.

It would be possible to lessen the likelihood that federal laboratories do not usurp the roles of universities by using the scheme I put forward in my testimony. A committee of the National Academy of Sciences would be formed to advise a mission agency on whether its research laboratories of the agency were doing appropriate work, or whether it was more appropriate to be done at a university. If so, then the agency directors should see that the laboratory moves that work outside.

4. Please describe the process, timing, and support necessary to convert a government-owned, government-operated laboratory from the civil service system to a personnel system similar to the one used by NCAR.

I do not have a well thought-out scheme for converting a GOGO laboratory to the personnel system used at NCAR. There are two different ways this could take place. The laboratory could become a contractor-operated laboratory, or the laboratory could stay in civil service but have a very different personnel system such as the Navy China Lake Lab has used in recent years.

In either case you want this process to proceed rather slowly because you are trying to improve the quality of work carried out and attract better scientists to the program. You need to protect the productive scientists who have been in the laboratory prior to this period. If a person has eighteen years in the civil service system, he almost certainly wants to continue working for two more years to get twenty years service, in order to achieve a certain retirement status. He would not want to be told suddenly to transfer to a new system with different retirement arrangements. I would suggest that probably a period between five and ten years be allowed to carry out the complete transfer. New employees brought into the laboratory should come in under the new personnel system. Old employees should have the privilege of retaining the present personnel status or transferring to the new personnel system.

There is a danger in having the new personnel system be inside a GOGO laboratory. If this personnel system is administered by the Office of Personnel Management in Washington, it may fail, as the Senior Executive Service has failed. A personnel system has to be allowed to function as designed. If OPM were to put artificial restrictions on top salaries or total amount of money that could be paid, or total number of personnel in the system, you will eventually arrive at another failed system, like the SES. Safeguards have to be built into the system to prevent this. I feel it would be better if the new personnel system in a GOGO was administered by the agency with only very general, broad overview from OPM.

Mr. RITTER. Our fourth witness is Dr. Franklin A. Long, former professor of chemistry at Cornell University and cofounder of Cornell's well-known Program on Science, Technology, and Society. Dr. Long will discuss the prospects and problems of Department of Defense support of research in U.S. universities.

Dr. Long, welcome to our Science Policy Task Force. We look forward to your testimony.

STATEMENT OF DR. FRANKLIN A. LONG, PROGRAM ON SCIENCE, TECHNOLOGY, AND SOCIETY, CORNELL UNIVERSITY, ITHACA, NY

Dr. LONG. Let me first say that it is really a very great pleasure and indeed an honor to be able to appear before this committee. It is an important committee, and you have done a good job. If by the kinds of things we say at meetings like this we can help you do a better job, we will all be happy.

What I want to talk about is something in general about Federal support of research and development in universities and then quite specifically relations between the universities and the Department of Defense which is, after all, the largest funder of our R&D in the Federal Government and deserves a little special attention.

As you have gathered and as you have implied, I spent a good many years of my life as an academic scientist in chemistry. My academic life has been very heavily at Cornell. However, I have been involved substantially in military activities. I spent 3½ years in a war laboratory during World War II and was a consultant and member of boards on a number of military activities. I was a member of PSAC for several years, and one of my assignments was to chair the Committee on Strategic Weapons.

So, my concern with and interest in the military is long standing. On the other side of the coin, I did spend 2 years as Assistant Director of the U.S. Arms Control and Disarmament Agency which is a different kind of view of the world. Finally, I spent several years as vice president of research and advanced studies at Cornell which gave me a kind of general feeling of the problems and opportunities for research in universities. It is from this background that I will be talking.

I won't follow my paper very closely and will try to condense materials. Let me start by commenting on the very obvious importance of the Department of Defense as a supporter of R&D. It is now getting to the point where it is spending about $40 billion a year on R&D, and that constitutes roughly two-thirds of all of the Federal funds that go into R&D, so it is a very substantial and very important agency.

All of this started dramatically, it seems to me, at the end of World War II. Before World War II, the military spent remarkably little on R&D. Their own budgets were pretty small, but even for those small budgets back in 1939, the military percentage of the total military budget that went into R&D was only 0.6 percent, a very modest amount indeed. What happened was that the clear importance of science-based technology during World War II caused a rethink, and DOD very promptly moved after the war to support research. Now, of course, not only is the budget $40 billion a year,

but that represents 12 percent of a very much larger total support for the DOD's programs. So, the evidence that R&D is important to the military is certainly very clear indeed.

One thing I do want to emphasize at the start is the degree to which DOD was a real pioneer in some of this. It established very quickly after the war the Office of Naval Research, and I think that was a truly and important agency. From the start, it agreed to support research at universities and did. It very quickly decided that it would respond to proposals sent into it from faculty by way of their university offices, so it was responding to the interests and desires of research people in universities. Then, it developed very quickly a peer review system for evaluating these. Both of these approaches have turned out to be very important and widely used through the years ever since.

For a little while, DOD was the major supporter of research in universities. That changed pretty rapidly, partly because other mission-oriented agencies like Health and Human Services and Agriculture and NASA and Energy—AEC in those days—began to support lots of research, and NSF came in very quickly. So, over the years, the importance of DOD as a supporter of research in universities has diminished but is still pretty significant.

This large Federal commitment to support research in universities, I think, has been a very great consequence, certainly to the universities and, I think, to the country. The agencies have effectively—and remember that the majority of these agencies that support research in universities are mission oriented. In spite of that, they have turned extensively to the universities for basic research and for long-range applied research, particularly in science and engineering but not limited to that.

Of course, from the point of view of the universities, there has been a very important synergism between their work and the work and desires of the mission-oriented agencies in that the research is a crucially central element of teaching in universities, particularly at the graduate student level, and so that this enhanced support for research strengthened a great deal the teaching capabilities of universities, and I would like to think that the research they produced was useful to the agencies themselves.

Someone used the phrase "research university" and that is exactly what was developed in this country—these large, vigorous universities in which research plays a really central role. It is clearly important still in teaching, but I think it is fair to say that the level and characteristics of university research has gone somewhat beyond even just the teaching responsibility.

A very substantial effort indeed, but what has the country got out of this large expenditure for research in universities? In the first place, they have clearly got large numbers of well-trained graduates and postgraduates. Scientists and engineers are one of the groups that we tend to think of, but in fact the development of a quality activity has permeated the whole university.

Another thing that this substantial funding of research has permitted universities to do is to move remarkably quickly into new fields of research. They really have been quick to pick up new ideas and to develop them and to make substantial efforts in them. The way they moved very quickly into computer research is one illus-

tration. The way they moved very quickly into genetic manipulation and now into biotechnology is another.

So, I think the country has something for this money that has been plowed in from the Federal agencies into the universities.

As a statistic, the universities of the country produce now about 70 percent of all of the publications in basic research that come out of the United States. They produce, and this is I think a more remarkable statistic, 55 to 60 percent of all of the publications in applied research. So, they really do make a large contribution, and by the kinds of criteria that you can use to measure the quality of research, it is quite clear that the product is a quality product. It is good research that they are doing.

In the paper, I included a slide which showed something about who were the major supporters from the Federal agencies for universities. It turns out that the major one is Health, Education, and Welfare with NSF a somewhat poor second and the Department of Defense a very close third. These are the two largest support agencies from the Federal Government. Note that two of them, at least, Health and Human Services and Department of Defense, are mission-oriented and so are the other significant ones, Agriculture, Energy, NASA, all have that character.

The figures for DOD in table 1 of the paper are somewhat interesting because DOD, which is third in support, is spending just a little less than $1 billion a year for fiscal 1985—as estimated but pretty close to correct. They are, interestingly, leader in the support of development in universities. In the main, what universities do is basic research and applied research. About, crudely, 65 percent, two-thirds, roughly, of their effort is in basic research. About 25 percent is in applied research, and the rest in development. Of that modest development component, DOD supplies something more than half of the development money, consistent, I think, with the picture we have of DOD as very much an applied agency interested in products.

The other table which was of some interest which is not in the paper—and I will give you just a few figures—DOD's total Federal expenditures—if you compare 1980 to 1985—total Federal expenditures have gone up in current dollars by something like 60 percent. During that period when total Federal dollars have gone up, the amount into universities and colleges has dropped. It dropped from in 1980, 37 percent to in 1985, 31 percent. And at least part of that goes directly with the fact that it was the DOD budgets that went up with particular rapidity during this period.

Another statistic is that during this period, the funds to universities from Federal agencies increased but only by a very modest rate of increase. Over the 5 years in constant dollars, the figures to universities went up only 7 percent. So, it is fairly close to constant over those 5 years.

Now, relations between these agencies, including the mission oriented agencies, have on the whole been remarkably good. Because of the synergism, the fact that they do have quite fundamentally different missions has not prevented them from working pretty well together, I think, in the main.

I am going to turn and talk about tensions between DOD and the universities, but it must be seen in context of overall, among all of the agencies, pretty good working relations between the two.

The role of the DOD in university programs is, as I noted, fairly modest. Only 2.5 percent of their total budget, which is now getting to be $40 billion, goes into universities. As a fraction of what the Federal agencies do, they do about 15 percent of their total support. So, they are an important agency for support of universities but not a dominant one.

It is true that in recent years, especially the last five, perhaps, tensions between DOD and the universities have increased quite a bit. I do want to talk about those. I will be talking about them from the point of view of the universities. If you had a DOD man sitting here, he would have another set of things to say about these tensions, but you will hear the university story.

It seems to me that there are five principal reasons why tensions have built up between DOD and the universities. The first one is DOD pressure to restrict dissemination of unclassified university research on the argument that it is, in their view, sensitive—sensitive in the sense that they would feel not very happy if the results of this admittedly unclassified research got into the hands of the Soviet Union and its allies.

The restrictions have shown up in about three different ways. One of them is the desire to restrict publication of some of these papers or to postpone it for a while. The second is the desire to cut down on the presentation of some of these papers at meetings of scientists which are pretty common. And the third is restrictions on the access of foreign scientists, particularly from the Soviet Union and the Warsaw Pact nations, to visit American universities. This has shown up not only in these explicit restrictions, but it is a fact that of all the agencies, the sort of pressures on the universities to modify their normal positions of open publication and independence of their publications is probably harder from DOD than I think any other agency, although the DOE, perhaps because of its own coupling to military programs, is also somewhat involved.

The second thing that leads to tensions has been, at least in recent times, a general push from DOD for getting more goal-oriented research out of the universities. The DOD sends in quite a lot of what are called requests for proposals, and many of them deal with pretty applied subjects. The particular illustration that has been in the news recently is the DOD interest in getting more work on the Strategic Defense Initiative, the star wars research program which is underway.

A third area for tension—and this is showing the universities' self-interest—it is that the universities are concerned that the very substantial buildup of funds for research in DOD and the tightening-up of funds for research of the more civilian-oriented agencies worries the universities that their trouble in getting support will increase as the fraction of the total Federal support goes up. There is a table in my paper that goes into that, and I won't go into details except to give you the total summary. It is for the 5 years between 1980 and 1985 again, and the important single figure is that the funds that have gone into the area of R&D for national defense

have gone up in those 5 years in constant dollars by 74 percent, a very handsome increase indeed. The funding for all other elements of the Federal support, all the other agencies, most all of which are civilian oriented, has in the same period gone down 17 percent. It is that difference in the direction of increased support which is worrisome to the universities.

I might note that the proposal that the "Star Wars" R&D program will grow very rapidly up to amounts like $6 or $8 billion a year in the next 2 or 3 years is part of that general worry that the universities may find it harder to get money for their fundamentally civilian-oriented programs.

There are two other reasons why universities are troubled by relations with DOD which are more political, I think it is fair to say. One of them is a concern among many people in universities about the approaches of the Department of Defense to their goals, and also the very strong emphasis on a military buildup, apparently very little interest in arms control or negotiations or alternative ways to search for national security, and a fairly aggressive stance against the U.S.S.R., including for the recent years at least a comparative neglect of arms control possibilities.

So, there is a sense of just doubt about the priorities which the DOD has. Now, as I am sure, the DOD, if it were here, would reject that and say that on the contrary they are entirely consonant with the best definition of national security, but a good many people in universities worry.

The fifth one is pretty much an internal matter, namely, that the universities, many people in universities, are worried about the balance of effort within their own institutions. Aren't they putting in too much money working on military related programs, even if it is long-range research, as compared to working on other ways for national security, arms control, unilateral moves—a dozen things that one might think of? That was a feeling, by the way, that was very high in the sixties in universities. It declined very much in the seventies, and now I think it is beginning to increase again.

So, these concerns are not trivial and they do influence relations. I do think, though, that you ought to put them in perspective in the following sense, that the average, typical university scientist who has a contract from the DOD in the main is quite pleased with it. That is to say, the negotiations from his point of view—not necessarily from the university's, I might say—but from his point of view are clear and there is a sense that DOD is interested in quality and once they have a research project, it goes along pretty well. So, the DOD is, I think, enlightened in many of its approaches to universities.

What is going to happen in the future? Well, in the first place, this kind of tension that I have mentioned could, of course, disappear or at least decrease quite considerably with certain modest changes. If, for example, the Reagan-Gorbachev Summit goes well and if the Soviet Union and the United States do enter into serious negotiations, I am sure that would make a great deal of difference in the feelings of many people. The new administration which will be coming along in a few years might not be so aggressively negative about arms control and disarmament possibilities.

Still, one has to come back to where DOD is in this total picture and where is it in the support of university programs. My own feeling is that if DOD is going to stay the dominant picture in Federal support of R&D and, in fact, if its fraction of moneys from the Federal are going to increase, as looks pretty likely given programs like SDI, I think this committee and, I hope, the DOD ought to think pretty seriously as to whether it should not actively be involved in giving more support to long-range research and to basic research in the universities—partly for its own interest and partly for the national interest.

Any university scientist if you asked that would say, "Gee, wouldn't it be nice if that could be done by NSF which we know and understand and which has this direct mission"—but that is probably unrealistic in these days of tight budgets. So, I would like to at least put a proposal on the table; namely, that there try to be a situation developed in which the universities do in fact have programs of support of basic and long research in universities for their general good and for the general good of the Nation, not because it tightly couples into any one goal or project of another.

It is the kind of thing that ONR did beautifully in the very early days of DOD, and I think a return to that kind of philosophy would be a very good thing. I would like to see, for example, explicit budgets among the armed services to support basic and long-range research and with moneys isolated to be used for that purpose so that it wasn't in competition with the goal-oriented programs. I would like to see the procedures that these units would use look very much like the ONR procedures of responding to initiatives, requests for support from university scientists and other scientists, utilizing peer review to examine quality and making awards on the basis of peer review, and to be happy, in fact, desirous, that the research be coupled with the teaching activity so that it is coupled into training of Ph.D's and postdoctorates.

I am heartened in thinking this is not a foolish thing to propose by a remark from a very longtime worker in the DOD for the DOD by the name of Al Flax who was once Assistant Secretary for the Air Force and has had many responsible positions. He wrote a paper for a book we did a few years ago, and he was contrasting the situation in the United States and the Soviet Union and said that his own strong belief as to why the United States was technically clearly superior to the Soviet Union in almost all aspects of military technology was that the United States was building on a much stronger civilian base of science and engineering. It is that that I think is the logical reason why the DOD might give some much more explicit support to that.

I could go on and talk about how much and a little bit in details, but I think I have said enough. I think it is important, incidentally, that DOD and the universities do work together. They have for many years. I would like to think that this recent buildup of tensions is a short-term thing and will minimize in the coming years, but it would be wrong not to call your attention to them at this point.

Thank you.

[The prepared statement of Dr. Long follows:]

Prepared for House Committee on Science & Technology

10/18/85

DoD Support of Research in US Universities:
Prospects and Problems

F.A. Long
Cornell University

The Department of Defense has much the largest program of research and development (R&D) of the US federal agencies, and its program has been growing rapidly in recent years. Historically, DoD has been involved in supporting R&D in universities since soon after World War II. Other federal agencies have followed DoD's lead, and support of university research by these agencies has been a major factor in the growth of scientific research in the US.

Even though among the federal agencies DoD no longer ranks as the largest supporter of university research, its interactions with universities, particularly with respect to restrictions on dissemination of research results, have been of special importance. This paper reviews the current status and future directions of these interactions from the point of view of the universities.

The development of interest by the US military in science-based research and development was dramatic. In the years before 1939 only a few million dollars of the military budgets went into research. In 1939 only 0.6% of US military budgets was allotted to R&D. The very large impact of science-based research on new weapons and new military materiel during World War II changed all that. Today US funding for research and development for the military amounts to about $40 billion per year, and constitutes roughly 12% of the total US budget for military activities. Since the US Department of Defense is clearly and emphatically a mission-oriented agency, one can firmly conclude that DoD sees research and development as a major component of the fulfillment of its mission.

DoD is not alone in recognizing the importance of research and development. The same applies to most of the other mission-oriented federal agencies: Health and Human Services, the Department of Energy, Agriculture and several others all see R&D as an essential element for their programs.

What is remarkable, however, is that these mission-oriented agencies have all seen the US universities as an important source for generating some of the research that they needed. As a consequence, the build-up of support of university research by mission-oriented federal agencies has been impressively large. Pre-1939, federal funds for research in US universities was negligible. Now federal funds constitute roughly two-thirds of the total support for research in US universities, and the majority of this support comes from mission-oriented federal agencies. The US military services were among the first to appreciate the contributions the university research might make to their missions, and the first substantial, and indeed continuing, program of federal support for university research was the Office of Naval Research (ONR) established just after World War II, with a major commitment to support to scientific research in universities.

ONR was a true pioneer. Not only was it the first federal agency to allot substantial funding for research in universities, it also established the procedures of permitting university scientists to submit individual proposals through their universities for support of their research, and then established a peer review mechanism to evaluate such proposals. These particular procedures are now deeply ingrained in the federal support system for US universities. I was involved in the ONR program for chemistry in the post-war years, and similarly involved in the program for the soon-established Air Force group called the Air Force Office of Scientific Research, and I can testify of the deep commitment of these groups to support first-

class research and of their complete willingness to utilize peer review in evaluating proposals. These were the trail-blazers for the NSF and other federal agencies.

For a few years after World War II support from the military services dominated federal support for university research, but this soon changed. Rapid build-up of research programs in the Atomic Energy Commission, in the National Institutes of Health, and in the new and important National Science Foundation, soon left the DoD in the position of being only a modest component of federal support of university research.

This willingness of mission-oriented federal agencies, as well as NSF, to support university research was invaluable to US universities, and their support played a major role in the rapid blossoming of what we now call the research universities of the US, those big, vigorous academic institutions where research plays a central role. Given that the missions of the universities and the agencies are quite different, it was probably inevitable that some tensions would build up between them, and they have, but it is remarkable that the tensions have in the main been fairly minor and sporadic. Both parties have, I believe, clearly benefited.

The primary function of research in universities has always been and remains to contribute to teaching. This applies especially to training of post-graduate students, where independent research by students constitutes a major component of their programs towards a Masters or Ph.D. degree. Because universities are the places where these advanced degrees are principally given, it is not surprising that the universities are overwhelmingly dominant in the production of research in US institutions of higher education.

An important element in relations between universities and research-supporting federal agencies is that overall the federal funding of research

has never covered the full costs of the research that they fund in universities. Put another way, the contributions of the universities to their research programs have always been large, and remain so. This is a problem that we have been studying at Cornell, and we are persuaded that the financial contribution from the universities to their research programs, including the federally-sponsored, is substantially underestimated. It is entirely proper that universities support research when it plays a significant role in their teaching programs. However, as university research programs expand to include the activities of large numbers of post-doctors, and more recently of substantial numbers of full-time research associates, and when new buildings must be put up to house the expanded research programs, then extensive university contributions to research costs become more and more of a burden, and less and less appropriate. For this reason alone, it is inappropriate for a university to become a "job shop" for research for outside groups, whether they be federal agencies or industrial concerns.

A closely related comment is that universities do, and in my judgement should, restrict themselves to research programs which are either for basic research or for long-range applied research. The central reason for research at universities is its coupling with advanced training of students, and the teaching process is by its very nature one in which deadlines and time-urgent demands such as are characteristic of development programs do not fit well. Equally important is that the teaching process demands open, uninhibited communication. Students and teachers must talk freely to each other, and cannot be bound by a hidden agenda or restrictions imposed from outside. University scholars also are routinely expected to communicate research results to the world by publication in the open literature. Consistent with these university objectives, the very large majority

of US universities have explicit provision against permitting any classified research on the university campus.

Within the restricted research activities that are appropriate to universities they have, however, become very important to the overall US R&D effort, and substantial support from federal agencies has been essential in universities attaining their current significance and stature. As it now stands, universities contribute roughly two-thirds of all publications from the US on basic research, and also contribute well over half of the nation's publications in applied research. The applied fields where university contributions are particularly important are clinical medicine, engineering, agriculture and biology.

The most important university contribution to the nation is probably the continuing output of highly-trained scientists, engineers and medical scholars, along with those from the other professional schools. The linkage between this output and that of research is close, however, since research is a major component of advanced training for graduate students and post-doctors.

Let me now turn from this general overview of relations between the federal agencies and US universities to the specific characteristics and problems that go with the relations between US universities and the Department of Defense. Among the operating agencies of the US government, the Department of Defense is pretty special. Its mandate, to maintain the military defense of the nation, is both deeply important and very visible. Its annual budget of roughly $300 billion is much the largest of the federal operating agencies. It has about three million employees, two million in the armed forces and one million civilians. Its procurement program of about $100 billion a year is comparably large. It purchases an immense spectrum of materials, ranging from aircraft carriers to army boots.

The DoD's program of research and development is dominant among federal agencies. It is now spending about $40 billion a year on R&D, and this constitutes about two-thirds of all federal expenditures for R&D. DoD itself spends about $10 billion per year for R&D and R&D management. Of the remaining $30 billion, the large majority goes to the companies within the US private industrial sector that work on R&D contracts from the military. The reason for this large program of commercial R&D is that the military's prime objective is to develop weapons and other products for its military forces, and the R&D by the private sector industry is usually an initial stage of projects that will ultimately lead to production of military hardware.

Relative to its large R&D budget, the amount of DoD-funded R&D in universities is comparatively small, under 3% of the total. DoD ranks only third among federal agencies in support of university research, being surpassed by the Department of Health and Human Services and by NSF. However as might be expected given its own rapidly growing budget, the contributions of DoD to university R&D have been increasing. In recent years DoD funds to universities for R&D have more than doubled, from $457 million in FY 1980 to $930 in FY 1985. In only a year or two DoD will have passed NSF to become the second-largest supporter of university R&D. In one category, support of university projects for development, DoD is already in first place. This comparatively large emphasis on development, is consistent with DoD's mission. Table 1 summarizes for FY 1985 the funding for research and development in universities of the six largest federal support agencies for university R&D.

Table 1

Funds for R&D in Universities in FY 1985 (est)
from Major Federal Support Agencies ($ in millions)
Data from NSF Report 84-336

Major Support Agencies	Basic Research	Applied Research	Develop-ment	Total
Dept. of Agriculture	150	149	2	301
Dept. of Defense	453	130	349	932
Dept. of Energy	197	112	18	327
Dept. of Health, Education and Welfare	1853	774	160	2787
NASA	174	37	25	236
National Science Foundation	976	56	0	1032
Total Funding from All Agencies	3834	1489	635	5958

The university faculty members that have received support from DoD have usually sought it and have welcomed it when it has come. Overall, however, there is considerable unease in universities about the increasing role that DoD is playing in university support, and a significant level of tension has arisen. There are several reasons, among which the following are probably the most significant:

- Pressures from DoD for increased classification of the results of university R&D that in DoD judgement are "sensitive"; along with this have come frequent calls for restrictions on presentation of research results at scientific meetings and restrictions on visits of scientists from Warsaw Pact nations to university laboratories.

- DoD desires for more goal-oriented research and development from universities; an example the recent DoD push for more R&D projects in universities for the Strategic Defense Initiative.

- Concern in the universities that the rapidly increasing federal funding of R&D for defense will lead to decreases in research support for civilian-oriented R&D.

- Skepticism and even antagonism in universities about many of DoD's goals and their approaches to them; the vigorous campaign for a space-based defense system against nuclear weapons is a current example.

- University concerns about an imbalance in university programs, stemming from a relative emphasis on military-related R&D as compared to the amount of university effort on alternatives to military approaches toward security, e.g., to arms control and to international negotiation; this concern was particularly strong at universities during the 1960s; it declined in the 1970s, but is again on the rise.

The following sections comment briefly on each of these areas.

A large fraction of the R&D that DoD supports is classified confidential or secret, and it is not surprising that DoD would frequently wish to see classified work done on university campuses by scholars with particular knowledge and interests. However, most universities decided at the end of World War II that classified research on campuses was incompatible with the openness that should go with teaching, and have barred classified research. Recently the DoD has put more emphasis on trying to restrict the spread of certain types of unclassified, i.e., open, results of university research. The usual reason was that the results of certain university research projects seemed "sensitive" to groups within DoD, who apparently believed that US security would suffer if the results were available to the Soviet Union or its allies. This has led to restrictions on presentations of research results at meetings, and a number of attempts to keep foreign scientists away from laboratories where potentially sensitive research (in DoD's eyes) was being done. The scientific community of US universities has reacted

strongly to these attempts, one indication being the well-known Corson Report from the National Academy of Sciences. In response to considerable concerns from universities, DoD has been restrained in applying restrictions, but their desire to restrict dissemination of some research results seems unchanged, and hence this topic remains a source of substantial tension between DoD and university scientists.

Among the federal agencies that support significant amounts of university research, the Department of Defense is clearly the most goal-oriented, i.e., the most focussed on getting useful products from applied R&D programs. As one illustration, DoD expenditures for basic research are only about 2% of their total R&D expenditures, whereas the overall average of the federal agencies is over 10%. In its grants and contracts for R&D in universities, almost 40% of the DoD projects fall in the category of development, an emphasis that is not shared by the other major federal supporters of university research. Since it is the results of development projects that are the most likely to be candidates for classification and for restriction of presentation or publication, the reason for some university concern is understandable.

It is equally understandable that universities are concerned that the rapidly increasing allotment of federal R&D funds to the DoD will lead to decreases in support of civilian-oriented research, which is the area that university research has mainly emphasized. The statistics on the trends in federal funds for R&D in recent years are given in Table 2, and amply demonstrate that as research funds for national defense have increased during recent years, funds for civilian R&D programs have decreased. From 1980 through 1985 federal R&D funding for national defense increased in constant dollar amounts by 74%, while R&D funding for the other functions, almost

all oriented toward non-military activities, dropped by 17%. It seems very likely that this trend will continue, and may even grow worse as the full impact of the large new R&D program for the Strategic Defense Initiative builds up.

In addition to these widely-shared university concerns on recent directions of the new R&D program for the military, there are two somewhat more political comments. First there is considerable skepticism and occasional antagonism within the university community about some of the goals and approaches of the Department of Defense. These feelings are by no means universally shared, but they are substantial and have been growing in recent years. In many cases this skepticism and doubt about DoD goals and approaches relates to the specific objectives just discussed; however, many go beyond this and are expressed as concerns that the DoD approach to international security is imbalanced, giving undue attention to the military

side of national security and too little to the side of negotiation and arms control. In a sense this is unfair, in that one should expect a particular agency, in this case the agency for the military, to emphasize its own particular area of responsibility. However, DoD representatives from such offices as that for International Security Policy have, in the eyes of many university faculty, been all too vigorous in denigrating the utility of negotiation and arms control measures. Hence the skepticism.

A related concern questions the balance of teaching and scholarship in universities on the broad topic of national and international security. The specific concern is that universities are giving comparatively much more effort and time to studies on the military aspects of national security, and much too little to political and social aspects and non-military methods to enhance security. This train of thought developed dramatically during the student dissidence in the 1960s. It had greatly diminished in subsequent years. However, it is now increasing in universities, and represents a serious train of thought and discussion. Once again, the most dramatic illustration is the feeling about the rapidly increasing R&D program called the Strategic Defense Initiative. Very few university scientists and engineers accept the feasibility of the goal of perfect defense against nuclear weapons as enunciated by President Reagan in 1983. The many skeptics argue that the Strategic Defense Initiative will not attain its goal, will be very costly, and may block progress in arms control negotiations for many years. Some then argue that university scholars, as a matter of principle, should not accept contracts to further the research programs of the SDI.

It is by no means certain that these essentially political feelings about the role of the Department of Defense and its R&D program will increase. If international tensions stay high, and if senior officials in

the administration seem reluctant to engage in serious arms control negotiations or other international negotiations, then the concerns could rise. However, they could also fall quite rapidly if, for example, there is substantial progress in the aftermath of the coming Reagan-Gorbachev summit meeting.

It is important to put this set of concerns in perspective. First, to the university scientists whose research is supported by a grant or contract from DoD, there is little difference in the negotiation or spending of funds from DoD from those of other federal agencies. The research proposal will originate with the scientist and will be forwarded to the DoD agency for their decision. The research, by the regulations of most universities, will be be unclassified. Second, for the typical US university DoD is not a major source of support. For example, for Cornell University, with total sponsored and budgeted expenditures for research in FY 1985 of about $200 million, only about 3% came from DoD.

A common question these days is whether DoD should, in its own interest and in the national interest, support more basic research, and more long-range and applied research in universities. With the Mansfield Amendment effectively out of the way, the opportunity to expand this sort of support clearly exists. My own belief is that DoD <u>should</u> substantially expand support of such research. However, there are important qualifications. University research of this type should not be supported as an element in a highly applied program. The programs should be established and operated from a conviction that the DoD and the nation need more such research, and further that the results should be published and available to all. In addition, DoD, and specifically the armed services, should establish or identify research management offices specifically charged to use explicitly allotted

funds to support university research. Procedures for support should be those initially pioneered by ONR: solicitation of research proposals from university scientists and engineers, and peer review evaluation as the essential element in identifying what projects should be funded. The central objective of the program should be generation of new scientific knowledge. Finally, the support program should be clearly independent of the goal-oriented R&D programs of DoD, SDI and others. How much DoD funding might appropriately be applied to support of pure research? Five percent of its total R&D funds might be a reasonable short-term objective. If the program is as important and as well received by universities as I think I would be, an ultimate goal might be somewhere between 7 and 10% of total R&D funding.

Most of the concerns and tensions between DoD and the universities really relate to the broader arena of restrictions on research dissemination and on contacts with foreign scientists that, although sometimes enunciated by DoD, probably emanate from a higher level of government, for example the National Security Council. Also, to the degree that they are successfully imposed, the restrictions would presumably apply to research programs supported by all federal agencies. Special concerns about DoD arise because it is usually the most visible agency in support of various restrictions. It is also particularly concerning because of its size and political influence.

The Strategic Defense Initiative of the DoD, and especially its emphasis on developing weapons to be deployed in space for defensive use, represents a rather special situation. It was initiated by the US president, and its objective is a major change in US nuclear strategy. It is a long-term program that will be in an R&D stage for several years before the feasibility of some of its major technologies is known. The SDI program is goal-

oriented and although formally called research, it is clearly applied, with many components that reasonable people might already call development. For these reasons university research on SDI projects seems inappropriate to many university scientists; other disagree, so that the issue is contentious.

The other concern in universities about the SDI program is that a several billion dollar add-on for SDI to the research budget of the Department of Defense will almost surely lead to a decrease in federal funds for civilian-oriented R&D, and that this will impact on the level university research. This need not happen, and concern about it is doubtless actuated in part by self-interest. However, there is a larger issue in that the need for US development of more high-technology industries is widely voiced in government and business circles, and research programs of universities are usually seen as an important source of the underlying basic and applied science for these new technologies.

What of the Future?

Pessimists will doubtless believe that what we have seen in recent years is a permanent change for the worse, in that the idea of restrictions on R&D results and on visits of foreign scientists will persist, and that the very large budget for military R&D will stay permanently high because of the greatly expanded DoD programs, and the addition of large funding for R&D for the Strategic Defense Initiative. Hence, it can be argued, the outlook for even constant funding for civilian R&D looks pretty grim. I am less pessimistic. The large DoD budgets are primarily a product of the current US administration, and are even now under attack. It is also conceivable that the coming Reagan-Gorbachev summit will start serious moves toward a genuine decrease in levels of nuclear missiles by the two superpowers. If serious moves are started in this direction, all sorts of possibilities

would open up. The critically important Anti-Ballistic Missile Trea could be updated and improved by the US and USSR. Military budgets could decrease. It is even possible to believe that the Star Wars program will turn out to be a bargaining chip in US-USSR negotiations.

Difficulties will remain. The large US budget deficit will impel any subsequent administration to keep a very tight rein on the federal budget, so that increased funding for civilian-oriented R&D may be hard to obtain, even if expenditures for R&D for the military decrease. However, the universities themselves can take actions that will make their position better. They can become more realistic in their analysis of the real costs of research in universities, and with that solid information improve their financing and management of R&D programs. Industry-university collaboration in research may grow significantly. But even with progress in all these, the need for substantial support of university research by the federal agencies will remain.

DISCUSSION

Mr. LUJAN [acting chairman]. Thank you very much, Dr. Long. It is an excellent presentation. It certainly gives the committee a much better view of the research relationship with the universities.

As you were discussing all of these, and you have touched on most of them, but certain thoughts keep going through my mind. One is the national laboratory research versus, if we may call it that, university research as it applies to basic or applied research and then the question of doing classified work at universities.

Could you tie those together for me? When we come up with a report on what our science policy should be, of course, we have to take a look at both ends of the equation, and it would be very helpful if you could take those three thoughts, the universities, labs, basic and applied, and the classified work, if you would just comment on that and tie it all together?

Dr. LONG. The large majority of U.S. universities have a policy that they will not accept classified research on the campuses. The reasons for that, I think, are exceedingly obvious. Having barriers for discussions between one professor and another and a student and his professor are not conducive to good teaching. The basic philosophy of academic scientists is that their research should be published in the open literature and available promptly to everyone. Again, classification is not compatible with that.

So, I personally think that the decision of most universities not to let classified research be on campus should stay. That, by the way, does not mean that lots of individual university scientists don't consult on a classified basis with military groups. I did that myself for many years. I probably still have classification which is a little inactive these days, but I think that eschewing of classified research on university campuses is a desirable thing.

As to the national laboratories, the first point is that the universities, of course, are more than a little involved in these.

For almost the last 40 years, I have been a trustee of something here in Washington called Associated Universities, Inc., and it runs Brookhaven National Laboratory and is involved in the big national radio astronomy programs in the same way. University people take responsibility for it, argue budgets, and are deeply involved in the support. I have taken sabbatical leaves at Brookhaven National Laboratory and have had students work there.

I think that the ones—I always forget this phrase—the GOCO's, of which Brookhaven is one, and the AEC ones in general, I think, saving one problem, have a lot of things going in making them be really good, desirable, effective laboratories.

The only thing that gets into trouble and one of the questioners mentioned this a little earlier is when they lose their mission. If there is some notion that they have an explicit mission and that begins to fade, that is troublesome. It is troublesome to anyone and, indeed, one sees a certain amount of it in universities when senior professors find that they are still working in a field which has got pretty dull. It is not quite a loss of mission but it is certainly a loss of an important mission.

I think that one ought to give—and I think this is very much in David Packard's philosophy—I think one ought to give a good deal

of responsibility to these laboratories to try to build themselves up. I think Mr. Hess' point of saying a strong director and a good deal of independence and a certain generalized accountability but not micromanagement is the way to go.

What you do when the mission really disappears is something else. Myself, I think it is not to this country's credit that we have closed so very few laboratories. Why shouldn't we close laboratories now and then if they have really lost their mission? Why not close or amalgamate and move on to others?

But I think that if one pays attention to missions and pays attention to giving the laboratories the independence they need in hiring and promoting, I think they can be very important.

I do think it is somewhat doubtful how important a role they will play in the competitive buildup of technologies that people talk about as they look upon our commercial situation vis-a-vis the Japanese or the Germans. A coupling of these national laboratories to industry is not all that easy. The picture that a Federal laboratory can develop a process and say "Here it is, Mr. Industry, why don't you take it over and run with it?" really misses the way that industry has worked. I am skeptical of that close linkage.

I do think much more consulting could and should be done by these good people in these Federal laboratories with industry. I would like to see closer relations. I think automatically to believe that they are going to play a large role in commercial technology development is a bit overstated sometimes.

Mr. LUJAN. Do you think that universities ought to run the laboratories as opposed to a private company running the laboratories?

Dr. LONG. I don't have any strong feeling on that. I think that Union Carbide ran Oak Ridge quite well for a good many years. I think that is a somewhat secondary point.

Mr. LUJAN. I come from New Mexico, and the University of California operates Los Alamos. Every time about contract renewal time, there is the question at the university level about whether the university should be operating a weapons laboratory. We always seem to renew the contract, but there is always that.

There is an interesting point that you made about classification and the researchers at universities wanting to talk to one another. One of the subcommittees, the Space Science Applications Subcommittee, was in the Soviet Union just last week. One of the things that we found was very interesting in that the working folks, the scientists, technicians, the program managers, all are most anxious to do cooperative work. As a matter of fact, one of them said to, I guess, their equivalent of the State Department, "If you will give me a visa, I will go tomorrow."

However, when we got to the political level, then we had a little different situation. So, I guess it is a natural tendency for scientists to want to share that information and, of course, that is our system. That is why we are advanced.

Dr. LONG. But I do think we could be, ought to be, more encouraging of collaborative research. There are a lot of areas where it is a natural and clearly would be mutually beneficial. Clearly, meteorology and all the things that have to do with the state of the

world as a total globe are things where collaboration would clearly be desirable, and exchange of data and so on.

I think that the space exploration area is an area where some more collaboration would be sensible. So, there are lots of areas where it won't work very much and lots of areas where I don't think it is much needed, but there are certainly some where it would be beneficial.

Mr. LUJAN. Yes, I certainly agree with you.

I don't have any further questions. We thank you for sharing your ideas with us.

With that, the task force stands recessed until tomorrow morning at 9:30 when we will meet in this room for our fifth hearing on science in the mission agencies and the Federal laboratories.

Thank you very much, Dr. Long.

[Whereupon, the task force recessed, to reconvene at 9:30 a.m., October 23, 1985.]

[Answers to questions asked of Dr. Long follow:]

1 November 1985

MEMORANDUM

To: House Committee on Science and Technology
From: F.A. Long FL.
Subject: Answers to questions forwarded to me on the basis of my testimony to the Committee on 22 October 1985

1) How might the optimum balance between civilian and military support for scientific best research best be determined?

Ideally the balance between these two modes of support would be determined by independent evaluation of what was needed for civilian support and what the military services needed for best doing their job. If one thinks specifically of research in US universities and asks this question, the situation is more complex because the majority of the support for university research comes from the mission-oriented agencies of the federal government. The question then becomes, should not these agencies, all of which depend on civilian research for some of their activities, portion out their support in terms of the science content of their missions and in terms of their size? Since DoD is the largest of the federal agencies, and since the science content of its effort is high, it should reasonably be expected to be a large contributor to university research.

2) To what extent does defense-supported research yield technology which is applicable to the civilian sector and vice versa?

The amount of "spin-off" that comes to the US civilian sector from military-supported programs of R&D is a much-discussed question. The percentages usually are given as somewhere between 10% and 20%, meaning that the spin-off is significant but not of major importance. In the reverse direction, the total amount of R&D supported by the civilian sector is so much larger and more pervasive than that of the military, that a better way of commenting is to say that the military activities are essentially built on the available civilian science and technology. A former Assistant Secretary of the Air Force put it this way: "Military systems development in the US... is heavily influenced not only by civilian science and technology, but also by civilian political, social, cultural and economic factors...."

3) Do decreases in civilian research relative to DoD support erode the scientific base, and thus national security?

Probably. Since research and development for the military is essentially built on the larger base of civilian science and technology, anything that erodes the latter will have a negative effect on DoD technical capabilities.

4) How will a "crash program" such as SDI affect the supply and demand of scientists, the scientific community, and the economy?

Analysts of the very large Apollo program to put men on the moon have given evidence that the large demand for scientists and engineers caused shortages, particularly of engineers, and also increased the salaries to a

degree that reacted on the overall civilian activities. The effect of the SDI program, in its R&D stages at least, will probably not be so strong. The total economy is much larger now, so that even if SDI reaches the projected levels of R&D funds (in the order of $6-8 billion per year) its relative impact will not be so great. Furthermore, it is likely that some part of the funds for SDI will come by decreasing other programs within the DoD budget. However, if the SDI program moves from research into development, and from development into production, the impact on the supply of engineers, computer scientists and other technical experts could be very substantial.

5) The US spends about 69% of the federal R&D budget on military R&D, whereas Japan spends about 5% of its government R&D budget on defense-related R&D, and West Germany spends about 15% of its government R&D funds on defense R&D. Does this put the US at a competitive disadvantage relative to Japan and West Germany?

The argument is persuasive that this large imbalance on relative funds spent for military R&D would lead to a less effective overall R&D program for the US, and perhaps therefore to a competitive disadvantage. Also, the fact that a substantial fraction of US scientists and engineers work on military projects would seem to point in the same direction. However, the question of what makes for a competitive industrial advantage of one country to another is so complex that I am hesitant to attribute a disadvantage simply to these factors.

6) Some university researchers argue that no university scholars should accept contracts to further the research programs of the SDI; how can such a stance be reconciled with the universities' tradition of academic freedom?

Arguments like this belong in the same category as the urgings on campuses that university faculty should "vote Democratic" or "vote Republican." They express a sentiment of a group, but are totally unbinding. At any university I know of, a faculty member may accept a grant or contract from any DoD agency, including SDI, and work on it assuming only that it meets the normal university criteria, e.g., to be unclassified and to contain no restrictions on publication. No question of academic freedom is involved in this.

7) Could you please estimate the amounts of basic and applied research supported by the Defense Department that are classified confidential or secret?

My estimate is that very little of the basic research supported by DoD is classified, and I suspect that only a fraction of the applied research is classified. The DoD classification makes a precise answer somewhat difficult. The latest report by the Undersecretary of Defense Research and Engineering, released in March 1985, states that out of a total RDT&E budget of $31,452 million, only $861 million were for research. Since roughly 2/3 of this was spent in universities, one can assume that the large fraction of this category was unclassified. In contrast, over 80% of the budget for RDT&E fell in the categories advanced development, engineering development and operational systems development, and it is reasonable to assume that the large fraction of these expenditures were classified.

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

WEDNESDAY, OCTOBER 23, 1985

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
SCIENCE POLICY TASK FORCE,
Washington, DC.

The task force met, pursuant to notice, at 9:39 a.m., in room 2325, Rayburn House Office Building, Hon. Don Fuqua, chairman of the task force, presiding.

Mr. FUQUA. The task force will be in order.

This is the fifth of our hearings on science in the mission agencies and Federal laboratories. This hearing will examine science policy in the Department of Defense.

The first of our distinguished witnesses will be Dr. Gerold Yonas, Acting Deputy Director and Chief Scientist of the Strategic Defense Initiative Organization. Dr. Yonas will explain the SDIO's policy on basic and applied research and the organization's relationship with the research community.

We are pleased to hear from you this morning, Dr. Yonas. We also have three other very distinguished witnesses from whom we will hear in the course of the morning.

STATEMENT OF DR. GEROLD YONAS, ACTING DEPUTY DIRECTOR AND CHIEF SCIENTIST, STRATEGIC DEFENSE INITIATIVE ORGANIZATION, WASHINGTON, DC

Dr. YONAS. Good morning. It is a pleasure to be here this morning and talk to you about some of the management issues in SDI related to science in the missions agencies and to answer your questions.

I would like to submit my written testimony for the record and to speak, hopefully more briefly, emphasizing some of the highlights in that.

Mr. FUQUA. We will make your statement in its entirety part of the record.

Dr. YONAS. Thank you.

Although the SDI is a rather new organization and it is confronting a very important challenge that has enormous implications for our Nation as well as the entire world, it is surprising when you realize how small the organization really is. This organization was established in 1984 and is a separate agency with its director, Lt. Gen. James Abrahamson, reporting directly to the Secretary of Defense. This organization began a little more than a year ago with a

staff of almost two dozen people with roughly a half a dozen technical people on the staff. The organization has been growing rapidly. Right now, we have close to 125 people, and we expect to be at a 200 person level at the end of this fiscal year.

Nevertheless, this is a program which is managing in fiscal year 1986 a budget, although we don't have an appropriation yet, hopefully in the vicinity of $2.7 billion, and we expect to do this with a relatively small staff.

I will talk some more about the management of the program later, but first let me emphasize the charter of the program. From our charter, we have the language that we are to manage and direct the conduct of research through advanced technology programs that will provide the technological basis for an informed decision regarding the feasibility of eliminating the threat posed by ballistic missiles and increasing the contribution of defensive systems to U.S. and allied security.

Now, this mission, this mission which is not development and is not deployment, is a mission to do research. However, this research is focused, and we expect that this focus will remain for the next 5 years, and that is to provide a sufficient understanding of the possibilities that advanced technology can bring to bear on these problems so that we can make a decision on going beyond the research phase.

If this research is successful, then we think the resulting defense system, although not performing in any sense perfectly, should nonetheless provide the basis for a transition to a safer and more secure world based on increasing reliance on defense. So, our aim is to have in the early nineties the data base. The data base will allow us to extrapolate from that data into a survivable, reliable, and cost-effective defense.

In order to acquire that data base, we think we will have to call upon all of the sectors of the scientific and engineering community. I am not sure how we are going to divide up those funds over that 5-year period, but in fiscal year 1985, we invested about 5 percent of those funds in the university community, about 20 percent of those funds in the Federal Government organizations—the national labs, Federal contracts, the research organizations—and the bulk of the funds, about 75 percent, in industry.

The mix of those funds is now preordained. It is defined through a competitive process. This competitive process is the keystone to the entire SDIO approach.We begin with analysis and system architectures, the backbone, the fundamental of the entire program, to define requirements. Those requirements then are used to create the areas and topics of research. We provide that requirement to the scientific and engineering community, and we request proposals. These proposals then are taken in, although we do get on occasion unsolicited proposals, and they are evaluated in terms of deliverables, cost, schedule. Then, within the fiscal limits imposed by the Congress, we proceed with the program.

That brings me to the next topic. Those fiscal limits have resulted in the requirement, the natural requirement, of course, to set priorities. Priority setting has continued to be one of the major activities that we carry out in this central management organization.

These priorities are not made in an exclusive way independent of other organizations in the Government. First of all, we consult with the various offices within the Secretary of Defense's organization. Then we deal with other relevant agencies, the Defense Nuclear Agency, the National Aeronautics and Space Administration, the Department of Energy [DARPA]. We have to and we consistently consult with the SDI commands within the armed services: the Army, Navy, and the Air Force. We consult with various offices of the executive branch, the Office of Science and Technology Policy, the OMB, the NSC, the State Department.

To show you the degree to which we coordinate the program, I want to point out that we recently carried out an extensive review with the White House Science Council of the Office of Science and Technology Policy. We carry out frequent reviews with the OMB, and we have a consultation and advice provided onsite to the negotiating team in Geneva. So, this priority setting is a complex process which involves coordination with many branches of the Government.

In order to facilitate this coordination, we have asked many of these organizations to form their own SDIO-related focal points. This allows us to carry out our central management role and deal with these agencies. Although we expect we will have probably 200 people at the end of this fiscal year in managing this program, we expect that at the same time, there will be well over 1,000 individuals in these various agencies managing these programs.

In fiscal year 1985, as a result of this decentralized management approach, we were able to begin procurement of roughly 1,000 contracts, and we were able to obligate almost 100 percent of the funds appropriated to us.

We think that this decentralized approach has been successful thus far only because of the total dedication and the very valuable cooperation of these many agencies. We are grateful to all of them for helping us manage this program.

The question of how you manage research in this kind of a complex environment and for rapidly changing technology is an interesting and a challenging process, and I think we are learning constantly. We are dealing with various agencies. We are dealing with complex problems. In order to do this, we have tried to rely on advisory groups to provide the breadth of experience and technical expertise into our decisionmaking process.

The most central advisory group in our program is the SDI Advisory Committee which consists of leaders of science and engineering throughout the country. That committee is chaired by Prof. Frederick Seitz. That committee meets quarterly and reviews various programs, makes suggestions for increasing certain activities or decreasing activities, and occasionally that committee forms subcommittees of its own to look in-depth at certain research areas.

In addition to that central committee, the SDI Advisory Committee, we also have committees in support of the battle management and command and control functions of our program. We have also several committees on sensors, innovative science and technology, and directed energy. We believe that this committee approach is very useful to providing the kind of detailed understanding and flexible management within a small central organization.

In addition to dealing with these committees that we charter and where we decide who is on these committees, we also believe that it is important in this kind of a program to consistently deal with not only our friends but also people who are opposed to the program who may have contrary views. So, we have tried to engage in detailed discussions with the proponents as well as the critics.

One interesting organization that has been very valuable to the defense research in this country for many years is the Jason organization. We realize that in the Jason organization we know there are people who are visible, vocal critics of the SDI.

Nevertheless, we have engaged the Jasons in looking at critical problems. We have given them detailed reviews and briefings of the key areas in our program. We have asked them to emphasize some of those areas that we call the long poles, the critical paths in the program. Last summer, we asked them to look at such issues as computer software and midcourse discrimination.

We also provide comprehensive briefings and information to other groups that are carrying on reviews of our program. We work very closely with the Office of Technology Assessment that recently completed a review of our program and published its report. Right now, we are working very closely with the American Physical Society. They are carrying out a review of the directed energy weapon program. We are working closely with them.

Now, let's get back to the management issues. This is a new program, as I mentioned, and it is approaching a very ambitious task. In proceeding with this program, we have not emphasized the process. We have emphasized results, and we have employed various funding mechanisms to get a very rapid startup. Because the diversity of the program, the fact that we are dealing with national laboratories, large industry, small business, universities, we find that innovation in getting these programs going has been extremely important.

We are also actively engaged at this time in discussions with Allied governments. In this area, what we are trying to do is to establish mechanisms for these Allied researchers to participate in the program. The goal there is to get the product in the most effective and most rapid and most cost-effective manner, and we think there is a great deal of technological capability that our Allies can provide to the program.

We think that our flexible management approach has allowed us to accelerate the startup over what might have been possible if we had spent the first year establishing a centrally-executed approach. Instead, we chose the centrally-managed and decentralized execution approach.

One of our problems has been a lack of hard data, a lack of a good way to measure the effectiveness of this startup, so we have had to create new ways to collect data to try to understand how well we are doing. One problem we have had is in measuring the rate of expenditures.

There are two traditional ways people talk about managing or monitoring the rate of expenditures. One is the rate of obligation—that is basically when you sign contracts. The other is the rate of expenditures—that is when you pay the bills. The problem is the

long lag time between when the work is done and when the bills are actually paid.

What we have done is to have gone out to our decentralized agencies who are actually executing the program and asked them to collect data on when work is actually completed, not necessarily when the bills come up through the chain of accounting into the system. What we have found is that this approach to determining when these non-cancelable commitments are made, when it is that the work is actually done and you can't pull back from the work but the bills aren't in, is extremely important in managing the program.

May I have the viewgraph?

We see, for instance, a very large disparity between the obligations and the expenditures. If we just looked at the expenditure curve, we might be much more reserved in terms of making our plans and our commitments for the future years. But we think that using this technique of noncancelable commitments in which we really determine what it is that has been done is extremely important and we would like to urge that the accounting procedure might be improved to provide more of a direct information to the Government in terms of what has been done, not necessarily what has been built.

FY85 TOTAL SDI FUNDS STATUS

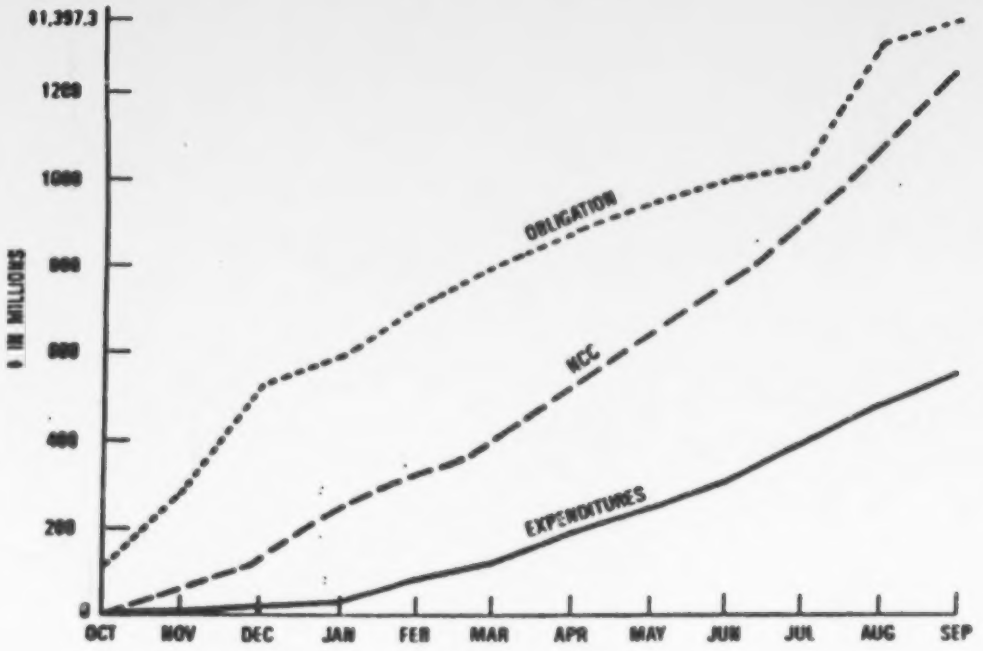

FIGURE 1

This lag time, I think, can give disturbing or false impressions of where you really stand in a program.

I wanted to give the impression that this is a fast-paced program, and we are trying to carry out innovative approaches to managing this program, but I don't want to give the impression that it is a crash program. In no way is it a crash program. It is an accelerated program. We like to think of our program as a horse race, a horse race among ideas. We like to think of the program as being a very fast track for this horse race, but we don't think it is a crash program.

We think that these techniques for getting on with competition, moving rapidly into new ideas, is a way to facilitate rapid technological advance. We think that is advantageous over some of the go-slow approaches which have existed and which have built up in the Government for some time.

We realize that, in this process, where we are pressing forward and making demands on the science and technology base, and where we are setting priorities where occasionally, within the limited funding, we have to make decisions that some people may think are premature. But we believe it is necessary to press forward and to not allow the time scale to continually stretch out with higher costs and less performance. We think it is important to admit the risk and press on.

In doing this, we have found in the community a tremendous amount of reserve capability, that there is a real basis of creativity and technical capacity that is really sitting there and waiting for a challenge. We believe that this capacity, this American technological capacity, one of the greatest strengths of this country, can really be brought to bear when it can focus its attention, and it is that focus that really makes the difference.

We think the SDI has provided the kind of focus which has an inherent basis of an ethical and a logical goal. It is that focus that we think is really allowing this community to bring its attention to bear and to move forward rapidly.

We also think this is an extremely timely moment. Because of the previous technological advances, we think we are ready to exploit those advances. They are in many areas: computer hardware, software, materials science, sensors, optics, propulsion, power supplies, lasers, accelerators—advances that have taken place over the last dozen or so years. We think we are ready to move forward with this focused approach to take advantage of this opportunity.

One of the most frustrating parts of managing and being involved in management of this program is not being able to really tap that capability that is really out there. We find that there are facilities that could be modified. We find that there are people out there ready to go, and we think that we can sustain a very rapid startup involving the entire technical community.

That includes the universities. Because of the research nature of this program, we think the universities can play an important role.

We think that there has been some misunderstanding in our relationship with the universities, and I wanted to talk about that. The next viewgraph shows the way we are organized. We have several principal elements of the program that deal with specific topics. The universities usually deal with these program elements

through a third party. For instance, they subcontract, or a minor part of the larger program is dealing with one of these major program elements.

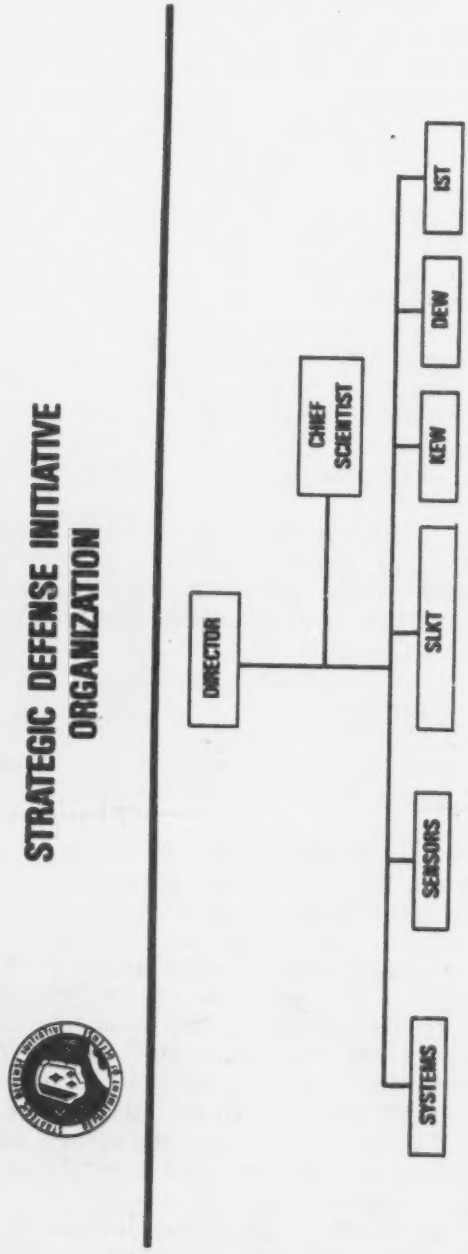

FIGURE 2

One part of our program, the Innovative Science and Technology Program, really has a special role in terms of the university relationship. Why have an innovative science and technology program?

I was involved in the Fletcher study in the summer of 1983 and Harold Agnew, who was the deputy in charge of that summer study coined an expression at that time in regard to high technology. As you know, Harold Agnew was the Director of Los Alamos and the president of General Atomics. He said the problem in technology is that the hogs always trample the piglets on the way to the trough. What he was talking about was the fact that large programs quite often, once they get started, squeeze out the opportunity for the really smaller innovative groups to really get started and to feed into this entire process.

So, when we started the SDI, we created an organization called Innovative Science and Technology which was to have specially earmarked funds fenced off, protected funds, no matter what happens in shortfalls or programs in the big activities, would have a few percent. Our goal is to have as much as 5 percent earmarked for this seed money, this seed corn of ideas to flow into the other program elements.

We are looking at many advanced areas, short wavelength lasers, advanced sensing and computing techniques, advanced materials such as composites and high-energy density propellants, molecularly-engineered dielectrics for very high-energy density energy storage, various techniques for innovative ways to store energy and condition power to very high levels. We find that there is a resident need to have this kind of—in the areas related to SDI—to have this independent and innovative research organization which can pursue these ideas, hopefully on a level that gets the programs going, that shows that these ideas are feasible and then transfers them to the program elements which are more specifically mission oriented.

Last spring, this organization, the Innovative Science and Technology organization, sponsored a conference for universities. Over 150 universities or academic institutions were represented. What came out of that were thousands of white papers. We asked for brief papers defining what it is, their ideas, what they wanted to do, how long it would take, and what would be the payoff.

What we found is that there really is a tremendous resident desire to proceed with pursuing these ideas on behalf of the SDIO. We think that speaks volumes about the program and the support from the university community and should be contrasted with some of the community that has in fact distributed petitions and spoken out against the program.

So, we don't think the academic community has just one voice, and I think that those thousands of white papers speak to at least part of that vocal community.

Now, that community does have concerns about the SDI. That concern has to do with their ability to publish their work. What we have done is emphasized in the Innovative Science and Technology organization that conduct of fundamental research—and the definition of fundamental research is available in the national security directive 189—and we believe that we can carry out this fundamental research. First of all, let me mention it is not just an emphasis

on the academic institutions, but we think this fundamental research can come from small business, from industry, from large industry. The point is that this fundamental research is, we think, vital seed corn for the ideas and for the technologies of tomorrow.

One of the problems that has arisen in regard to pursuing this fundamental research is the fact that when we began this program, we established the IS&T with the category of 6.3 which is a budgetary category within the Department of Defense. Normally, that work going on under 6.3 is normally not allocated for fundamental research. We tried to clarify that. Hopefully, we have clarified that issue in memos which have been published by our group, and we expect that as we proceed will provide the universities with the opportunity and the freedom for free publication of their fundamental research.

The second issue that the universities have raised with us is that because of the fact that we announced the award of grants, we apparently incorrectly implied some political support from the academic institutions ourselves. I would like to say categorically that was never our intention. We did not intend to somehow give the impression that we had received political support from the institutions.

Basically, what we have tried to do is create consortia, groups of researchers working at universities or academic institutions, not consortia of institutions themselves. In the future, we will be very careful to emphasize in our public statements that the research is being carried out by consortia of researchers and not consortia of institutions.

Another issue has to do with availability of the manpower to actually pursue this activity of research. Clearly, this is a concern for the entire Department of Defense. In fact, Don Carter testified on October 2 on the availability of personnel for the entire DOD, but I wanted to call your attention to a House Appropriations Committee study that was carried out last year in which they used their independent investigating staff to look at the requirements for SDI in particular. They concluded that the SDI did not tax the available resource base.

Now, there are clearly some areas of specific need, some areas where there are some requirements for additional personnel. For instance, one is in optical science. Here we have only two institutions that award the Ph.D in optical sciences, the University of Arizona and Rochester University. Here we do have some concern about available personnel. But we think there is a great deal of flexibility in the community. People trained broadly in engineering and science can move over to other fields where there are needs. This flexibility, we find, is one of the strengths in our technological society in this country, the fact that we have individuals at large companies that go off and form small business, professors at universities that move around. We have the flexibility to retrain and to fill the needs in research organizations. I wouldn't take as a given that if we don't have at a particular point in time the people in a certain field, because in our flexible and mobile society, people move and they fill in those gaps. We have a marketplace that works.

The real limitations in the program are really the realistic limitations on the rate at which technology can move. It can only move so fast. And the real limitations which are provided by fiscal constraints, how much money is available.

Right now, we don't think that the ABM Treaty compliance issues limit the pace at which the program can move forward. In fact, we plan to carry out this research in compliance with the ABM Treaty. In fact, the President recently announced or reemphasized his desire that we use the more restrictive interpretation of the ABM Treaty as we proceed with our research.

Let me say one word about the Federal laboratories. I think a very useful document is the Federal laboratory review panel report that was issued in May of 1983 that spoke to the role of the Federal laboratories. We believe that the Federal laboratories have an important role to play in our program in those special areas where, because of their unique or capital intensive or long term multidisciplinary nature, have a special role to play in the program. We are going to continue to rely on the national labs.

Let me say, finally, that we think there are important attributes that are necessary to pursue this program. One is the dedication to get the answer. Second is the creativity that is needed in this kind of a new field of exploration. Finally is a healthy skepticism, because going in we know there are going to be a lot of approaches which are not going to pan out.

We think we have, in pursuing this program, these three attributes of dedication, creativity, and skepticism. We also think because of the strong motivation that is provided by the goal, by the ethical and logical goal to pursue a more secure and stable future, we think the SDIO is on its way to getting the answer for the country.

Thank you.

[The prepared statement of Dr. Yonas follows:]

STATEMENT ON

THE STRATEGIC DEFENSE INITIATIVE SCIENCE IN THE MISSION AGENCIES & FEDERAL LABORATORIES

BY

DR. GEROLD YONAS

ACTING DEPUTY DIRECTOR AND CHIEF SCIENTIST

STRATEGIC DEFENSE INITIATIVE ORGANIZATION

BEFORE THE

SCIENCE POLICY TASK FORCE

COMMITTEE ON SCIENCE & TECHNOLOGY

HOUSE OF REPRESENTATIVES

99TH CONGRESS, FIRST SESSION

OCTOBER 23, 1985

MR. CHAIRMAN:

I WANT TO THANK YOU FOR GIVING ME THE OPPORTUNITY TODAY TO ADDRESS YOU ON THE SUBJECT OF "SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES."

MISSION

ALTHOUGH THE SDIO IS UNDOUBTEDLY ONE OF THE NEWEST AND SMALLEST OF THE RESEARCH ORGANIZATIONS WITHIN THE FEDERAL GOVERNMENT WE ARE CONFRONTING A TECHNICAL CHALLENGE THAT HAS ENORMOUS IMPLICATIONS FOR OUR NATIONAL, AND INDEED WORLD SECURITY AND SURVIVAL. WE WERE ESTABLISHED AS A SEPARATE AGENCY OF THE DEPARTMENT OF DEFENSE IN 1984, AND OUR DIRECTOR, WHO IS APPOINTED BY AND REPORTS DIRECTLY TO THE SECRETARY OF DEFENSE, IS LIEUTENANT GENERAL JAMES ABRAHAMSON. LITTLE MORE THAN ONE YEAR AGO WE HAD A STAFF OF TWO DOZEN PEOPLE, INCLUDING SIX PROFESSIONAL TECHNICAL PEOPLE AND TODAY WE HAVE ROUGHLY 125 PERSONNEL AND HAVE ESTABLISHED A PLAN TO REACH A LEVEL OF 200 PEOPLE BY THE END OF THIS FISCAL YEAR.

THE SDI MISSION IS SUCCINCTLY STATED AS FOLLOWS:

> SDIO SHALL MANAGE AND DIRECT THE CONDUCT OF RESEARCH THROUGH ADVANCED TECHNOLOGY PROGRAMS THAT WILL PROVIDE THE TECHNOLOGICAL BASIS FOR AN INFORMED DECISION REGARDING FEASIBILITY OF ELIMINATING THE THREAT POSED BY BALLISTIC

MISSILES AND INCREASING THE CONTRIBUTION OF DEFENSIVE SYSTEMS TO U.S. AND ALLIED SECURITY. THE PROGRAM SHALL PROVIDE OPTIONS FOR NEAR-TERM DEPLOYMENT OF LIMITED BALLISTIC MISSILE DEFENSES. THIS PROGRAM WILL BE CARRIED OUT IN FULL CONSULTATION WITH OUR ALLIES AND IN COMPLIANCE WITH ALL EXISTING TREATY OBLIGATIONS.

RESEARCH BUDGET

THE COMMITTEE HAD ASKED FOR AN INDICATION OF HOW MUCH OF THE SDIO BUDGET IS SPENT ON RESEARCH. THE ANSWER IS ALL OF IT. THE PRESENT MISSION OF THE SDIO IS RESEARCH, BOTH BASIC AND APPLIED. THE RESEARCH, HOWEVER, IS FOCUSED. THE FOCUS FOR THE NEXT FIVE YEARS IS TOWARD A SUFFICIENT UNDERSTANDING OF THE POSSIBILITIES THAT NEW ADVANCED TECHNOLOGIES CAN BRING TO BEAR IN PROVIDING A DEFENSE AGAINST ICBM'S. IF OUR RESEARCH IS SUCCESSFUL, THE RESULTING DEFENSE, WHILE PERFORMING LESS THAN PERFECTLY, SHOULD NONE-THE-LESS PROVIDE THE BASIS FOR A TRANSITION TO A SAFER AND SECURE WORLD BASED ON "INCREASING RELIANCE ON DEFENSE." WE HAVE NOT STRAYED FROM THE ORIGINAL GOAL SET FORTH BY THE PRESIDENT IN MARCH 1983. OUR AIM IS TO HAVE IN HAND BY THE EARLY 1990'S A DATA BASE THAT, IF IT PROVES THE MISSION IS FEASIBLE, COULD EXTRAPOLATE INTO A SURVIVABLE, RELIABLE, COST-EFFECTIVE STRATEGIC DEFENSE FOR THE UNITED STATES AND ITS ALLIES.

WE WERE ASKED TO ADDRESS THE QUESTION OF HOW OUR BUDGET WAS DIVIDED AMONG UNIVERSITIES, GOVERNMENT LABORATORIES, AND

INDUSTRY. THE DIVISION OF THE FY 1985 BUDGET OF $1.3973 BILLION WAS AS FOLLOWS:

UNIVERSITIES	5%
GOVERNMENT (NATIONAL LABS + FEDERAL CONTRACT RESEARCH CENTERS + ADMINISTRATIVE COSTS)	20%
INDUSTRY	75%

THE MIX OF THESE FUNDS IS DETERMINED PRIMARILY THROUGH A COMPETITIVE PROCESS WHEREBY SPECIFIC MISSION REQUIREMENTS GENERATE AREAS OF RESEARCH THAT ARE DEFINED FOR THE SCIENTIFIC AND ENGINEERING COMMUNITIES, AND PROPOSALS TO PERFORM THIS RESEARCH ARE REQUESTED. (ON OCCASION, INDEPENDENT UNSOLICTIED CONCEPTS ARE PROVIDED TO US BY THE TECHNICAL COMMUNITY.) THOSE CONCEPTS THAT ARE EVALUATED TO BE MOST RELEVANT AND PROMISING IN TERMS OF DELIVERABLES, COST AND SCHEDULE, ARE FUNDED WITHIN THE FISCAL LIMITS IMPOSED BY CONGRESS.

FUNDING PRIORITIES

PRIORITIES FOR FUNDING ARE SET BY THE SDIO DIRECTOR IN CONSULTATION WITH: (1) THE OFFICE OF THE SECRETARY OF DEFENSE; (2) OTHER RELEVANT AGENCIES (E.G., DEFENSE NUCLEAR AGENCY (DNA), NATIONAL AERONAUTICS AND SPACE ADMINISTRATION (NASA), DEPARTMENT OF ENERGY (DOE), ETC.); (3) SDI RESEARCH COMMANDS OF THE ARMED FORCES; AND (4) THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY

(OSTP), OFFICE OF MANAGEMENT AND BUDGET (OMB), NATIONAL SECURITY COUNCIL (NSC), AND STATE DEPARTMENT. IN ORDER TO FACILITATE THESE INTERACTIONS, MANY OF THESE ORGANIZATIONS HAVE ESTABLISHED AN INTERNAL FOCAL POINT TO DEAL WITH SDI ACTIVITIES. THE SDI PROVIDES CENTRAL MANAGEMENT BY SETTING OVERALL DIRECTION, PRIORITIES, AND BUDGETS, AND THE AGENCIES LISTED ABOVE PROVIDE DECENTRALIZED EXECUTION OF THE VARIOUS PROGRAM ELEMENTS. THESE AGENCIES SERVED AS THE PROCUREMENT AGENT FOR MOST OF THE OVER 1000 CONTRACTS PLACED IN FY 1985.

SOME RESEARCH PROJECTS ARE REVIEWED WITHIN THESE AGENCIES, OTHERS ARE REVIEWED BY PANELS OR INDIVIDUALS OUTSIDE OF THE GOVERNMENT. THE ONE AREA MANAGED DIRECTLY BY THE SDIO IS SYSTEMS ANALYSIS (THE ARCHITECTURE DEFINITION TASK) AND AN AREA MANAGED ALMOST ENTIRELY OUTSIDE OF THE SDIO IS THAT OF INNOVATIVE SCIENCE AND TECHNOLOGY.

ADVISORY COMMITTEES AND WORKING GROUPS

THE SDIO HAS CREATED A NUMBER OF ADVISORY GROUPS. THE SDI ADVISORY COMMITTEE (SDIAC), WHOSE MEMBERSHIP IS SHOWN BELOW, MEETS QUARTERLY AND HELPS REVIEW THE PROGRESS OF VARIOUS PROGRAM ELEMENTS AND INDICATES AREAS REQUIRING EITHER INCREASED OR DECREASED RESEARCH EMPHASIS. IN FACT THIS COMMITTEE HAS, UPON OCCASION, ORGANIZED ITS OWN SUBCOMMITTEES TO DELVE IN GREATER DEPTH INTO SUBJECTS OF TIMELY INTEREST AND IMPORTANCE TO THE SDI MISSION. THE SDIAC REPORTS DIRECTLY TO THE AGENCY DIRECTOR.

SDI ADVISORY COMMITTEE MEMBERSHIP

DR. FREDERICK SEITZ, CHAIRMAN

MR. JAMES C. ELMS

MR. ROBERT R. EVERETT

DR. JAMES C. FLETCHER

DR. HANS MARK

DR. RICHARD MONTGOMERY

DR. WILLIAM NIERENBERG

DR. MARSHALL ROSENBLUTH

GENERAL BERNARD SCHRIEVER (USAF, RET)

DR. ROBERT SPROULL

DR. EDWARD TELLER

IN ADDITION, THERE ARE SEVERAL ADVISORY GROUPS WORKING AT OTHER LEVELS IN THE SDIO. A LISTING OF THESE WOULD INCLUDE: THE EASTPORT GROUP (BM/C^3 SOFTWARE), SCIENCE AND ENGINEERING SUPPORT GROUP (SENSORS), GOVERNMENT COORDINATING PANEL (IS&T), AND THE DIRECTED ENERGY PROGRAM ASSESSMENT GROUP (DEO). THESE GROUPS PROVIDE INDEPENDENT REVIEW AND ADVICE TO SDI MANAGEMENT IN SPECIFIC RESEARCH DISCIPLINES.

IT IS VITAL TO THE GOOD HEALTH OF ANY RESEARCH ORGANIZATION THAT IT MAINTAIN CONSTANT CONTACT WITH "UNBIASED" OUTSIDE OBSERVERS WHOSE COMPETENCE AND EXPERTISE CAN BE QUICKLY BROUGHT TO BEAR ON MAJOR ISSUES. CONSTRUCTIVE ENGAGEMENT WITH BOTH FRIENDS AND CRITICS IS IMPORTANT. DURING FY 1985 WE ALSO

SUPPORTED THE JASONS WHO REVIEWED SEVERAL SDI SUBJECTS WITH SPECIAL EMPHASIS ON SUCH KEY PROBLEMS AS DISCRIMINATION AND COMPUTER SOFTWARE. IN ADDITION, WE PROVIDED INFORMATION TO THE OFFICE OF TECHNOLOGY ASSESSMENT, AND THE AMERICAN PHYSICAL SOCIETY FOR USE IN THEIR RESPECTIVE EVALUATION REPORTS.

MANAGEMENT

IN THE SDIO, DUE TO ITS RELATIVELY "NEWNESS," AND IN KEEPING WITH A PHILOSOPHY EMPHASIZING RESULTS RATHER THAN PROCESS, WE HAVE USED VARIOUS FUNDING MECHANISMS AND PROGRAM MANAGEMENT TOOLS TO OBTAIN SPECIFIC RESEARCH RESULTS. AT THE PRESENT TIME SDI EFFORTS ARE PURSUED IN NATIONAL LABORATORIES, LARGE INDUSTRY, SMALL BUSINESSES, AND UNIVERSITIES. WE ARE ALSO ACTIVELY ENGAGED IN DISCUSSIONS WITH ALLIED GOVERNMENTS IN ORDER TO ESTABLISH MECHANSIMS TO ENGAGE OUR ALLIES' TECHNICAL CAPABILITIES IN SOLVING THE MOST PRESSING OF THE SDI RESEARCH PROBLEMS.

OUR MANAGEMENT APPROACH HAS ALLOWED THE SDIO TO ACCELERATE OUR START UP OVER WHAT WOULD HAVE BEEN POSSIBLE GIVEN A MORE CENTRALLY EXECUTED PROGRAM. IN THIS REGARD I WOULD LIKE TO DISCUSS WITH YOU FOR A MOMENT A NEW MEASURE OF EFFECTIVENESS THAT WE HAVE RECENTLY EMPLOYED IN SDIO, AND THAT WE BELIEVE MORE ACCURATELY REFLECTS COMMITTED PROGRAM FUNDS. IN MOST NEW PROGRAMS THE ANALYSIS AND MONITORING OF FUNDS IS HAMPERED BY A LACK OF REAL TIME INFORMATION ON THE STATE OF COMMITMENTS. TO

REMEDY THIS WE HAVE DONE TWO MAJOR THINGS. FIRST, WHENEVER IT BECOMES APPARENT THAT A PARTICULAR RESEARCH PROGRAM HAD PROMISED MORE THAN IT COULD LEGITIMATELY DELIVER IN A GIVEN YEAR, WE HAVE REALIGNED FUNDS IN SUCH A MANNER AS TO ENHANCE THE PROJECTS WHICH COULD USE ADDITIONAL FUNDS. IT IS EXTREMELY IMPORTANT TO RETAIN THIS KIND OF FLEXIBILITY IN A FAST PACED PROGRAM SUCH AS THE SDI.

SECONDLY, WE HAVE DEVELOPED, WHAT WE BELIEVE TO BE A NEW MEASURE OF PROGRAM EFFECTIVENESS. THIS NEW MANAGEMENT TOOL IS CALLED NON-CANCELABLE COMMITMENTS. TO UNDERSTAND ITS UTILITY, I WILL TRY TO DESCRIBE ITS FUNCTIONS BY SHOWING THE LIMITATIONS WHICH COME FROM USING THE TRADITIONAL BUDGETARY MILESTONES. KEEPING IN MIND THAT OUR AIM IS TO QUICKEN THE PACE OF OUR PROGRAM BY PUTTING RESOURCES TO THEIR MOST PRODUCTIVE USE, ONE FINDS THAT TRADITIONAL MILESTONES (I.E., OBLIGATIONS AND EXPENDITURES) WHILE STILL IMPORTANT, ARE INADEQUATE. WHY?

OBLIGATIONS:

- ONLY INDICATE WORK IS READY TO BEGIN, NOT THAT IT BEGAN
- INDICATE THE USER HAS BECOME LEGALLY LIABLE FOR PAYMENT OF COSTS
- OCCUR WHEN CONTRACTS ARE EXECUTED OR PROJECTS ACCEPTED

EXPENDITURES:

- OCCUR ONLY AFTER CONSUMPTION...SOMETIMES YEARS LATER
- REPRESENT ACTUAL PAYMENT FOR GOODS/SERVICES

NEITHER OF THESE CATEGORIES BEAR A RELATIONSHIP TO THE "EFFECTIVENESS" OF THE USE OF RESOURCES.

WE BELIEVE NONCANCELABLE COMMITMENTS MAY BE OF GREATER IMPORTANCE, FOR MANAGERS, (NOT NECESSARILY ACCOUNTANTS). NONCANCELABLE COMMITMENTS REPRESENT COSTS AND LIABILITIES INCURRED FOR GOODS AND SERVICES RECEIVED, OTHER ASSETS ACQUIRED, AND PERFORMANCE ACCEPTED, WHETHER OR NOT PAYMENT HAS BEEN MADE. THIS IS A FINANCIAL PARAMETER MORE CLOSELY RELATED TO PERFORMANCE.

NONCANCELABLE COMMITMENTS (NCC):

- REPRESENT WORK ACCOMPLISHED
- INCLUDE INCURRED DEBTS
- INCLUDES BOTH BILLED AND UNBILLED MATERIALS, DELIVERIES AND RESEARCH EFFORTS.
- OCCUR WHEN GOODS/SERVICES ARE RECEIVED, OR WHEN PERFORMANCE IS ACCEPTED...WHETHER OR NOT PAYMENT IS MADE.

IT IS NOT CLEAR THAT THE USE OF NONCANCELABLE COMMITMENTS IS USEFUL FOR EVERY TYPE OF ORGANIZATION, SO I AM NOT HERE TODAY TO RECOMMEND ITS WIDE SPREAD USE OR ADOPTION. ITS USE IS AN EXPERIMENT ON THE PART OF SDIO MANAGEMENT TO TRY TO BE MORE EFFECTIVE THROUGH THE IMPLEMENTATION OF INNOVATIVE MANAGEMENT TOOLS.

AS AN EXAMPLE, I SHOW IN FIGURE #1, THE FY 1985 TOTAL SDI FUNDS STATUS AS A FUNCTION OF MONTHS INTO THE FISCAL YEAR. WE,

AS A NEW AGENCY, HAVE SOMETIMES COME UNDER CRITICISM THAT WE HAVE NOT AND/OR CANNOT EFFECTIVELY ALLOCATE OUR BUDGET RESOURCES AND THAT THE PROGRAM MAY NOT BE WELL DIRECTED. WHILE NCC DOES NOT MEASURE HOW WISELY THE FUNDS ARE COMMITTED, IT DOES AID THE SDI MANAGEMENT TEAM IN DISCERNING WHETHER OR NOT RESOURCES ARE BEING COMMITTED IN A TIMELY FASHION BY OUR PROGRAM MANAGERS OUT IN THE FIELD. LET ME EMPHASIZE THAT THE USE OF NCC DOES NOT REPLACE THE NEED TO MEASURE A PROGRAM BY ITS RESULTS. THE RESULTS ARE WHAT REALLY COUNT AND I WILL HAVE MORE TO SAY ON THAT LATER IN MY TESTIMONY.

TO COME BACK ON TRACK FROM THIS BRIEF DIGRESSION, LET ME ATTACK THE QUESTION OF HOW POLICY AND BUDGET AGENCIES INTERACT WITH SDIO. THE WHITE HOUSE SCIENCE COUNCIL, WHICH REPORTS DIRECTLY TO DR. GEORGE KEYWORTH, THE DIRECTOR OF THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY (OSTP), RECENTLY PERFORMED A COMPREHENSIVE REVIEW OF THE SDI TECHNICAL PROGRAM. IN ADDITION, WE WORK CLOSELY WITH OMB TO COORDINATE EFFORTS AMONG AGENCIES AND TO MAXIMIZE PROGRAM EFFECTIVENESS.

YOU HAVE ASKED FOR THE IMPACT OF "CRASH PROGRAMS" ON OUR PRODUCTIVITY AND RESOURCES. SIMPLY PUT, NONE OF THE SDI IS ON A CRASH PROGRAM. WE ARE ON ADMITTEDLY A VERY FAST TRACK IN WHAT GENERAL ABRAHAMSON HAS SAID MORE THAN ONCE, IS A HORSE RACE. WE BELIEVE FAST PACED BUT CONTROLLED PROGRAMS, IF ALLOWED

FLEXIBILITY, CAN PRODUCE MORE RESULTS PER DOLLAR INVESTED THAN MOST OF THE "GO SLOW" APPROACHES. HOWEVER, ONLY THE TEST OF TIME WILL REALLY SHOW WHETHER THIS APPROACH TO MANAGEMENT IS PRODUCTIVE ENOUGH TO GET THE JOB DONE.

WE HAVE DETECTED A GREAT DEAL OF RESERVE CAPABILITY AND CREATIVITY WAITING FOR A CHALLENGE. WE BELIEVE THAT AMERICAN TECHNOLOGICAL CAPACITY IS MOST PRODUCTIVE WHEN IT CAN FOCUS ITS ATTENTION ON A GENERALLY ACCEPTED GOAL. THE SDI HAS PROVIDED NOT ONLY THE ETHICAL AND LOGICAL GOAL OF A DEFENSE AGAINST BALLISTIC MISSILES, BUT IT HAS COME AT A TIME WHEN AMERICANS, AND HOPEFULLY THE WORLD, ARE READY TO EXPLOIT THEIR RECENT TECHNICAL ADVANCES. MANY RECENT ADVANCES IN COMPUTER HARDWARE AND SOFTWARE, MATERIALS SCIENCE, SENSORS, OPTICS, PROPULSION, POWER SUPPLIES, LASERS, AND ACCELERATORS ARE READY TO BE EXPLOITED RAPIDLY IN BEHALF OF SDI GOALS.

EXTRAMURAL RESEARCH PERFORMERS

LET ME NOW SHIFT GEARS AND ADDRESS THE SDIO/UNIVERSITY COMMUNITY INTERACTION. THERE HAS BEEN SOME PUBLICITY WITH REGARD TO THIS RELATIONSHIP AND I WOULD LIKE TO TAKE THIS OPPORTUNITY TO SET THE RECORD STRAIGHT.

SOME UNIVERSITIES RECEIVE FUNDING FROM THE PRINCIPAL DIRECTORATES SHOWN IN FIGURE #2, USUALLY THROUGH THIRD PARTY SUBCONTRACTS. BUT BY FAR THE PREPONDERANCE OF UNIVERSITY

RESEARCH ACTIVITY WILL BE FUNDED THROUGH A SEPARATE BUT CROSS CUTTING ELEMENT OF SDIO CALLED THE OFFICE OF INNOVATIVE SCIENCE AND TECHNOLOGY (IST).

THE GOAL OF OUR INNOVATIVE SCIENCE AND TECHNOLOGY PROGRAM IS TO ESTABLISH SCIENTIFIC FEASIBILITY OF REVOLUTIONARY CONCEPTS, CONCEPTS WITH POTENTIAL FOR FULL SDI TECHNOLOGICAL DEVELOPMENT. THIS FORWARD-LOOKING OFFICE HAS A BROAD RESEARCH CHARTER WITH FOCUSES ON SUCH ADVANCED DIRECTED ENERGY CONCEPTS AS GAMMA RAY LASERS, ON NOVEL SENSING AND DATA PREPROCESSING TECHNIQUES, ON ADVANCED MATERIALS FOR SPACE APPLICATIONS, INCLUDING MOLECULARLY ENGINEERED DIELECTRICS, ON INNOVATIONS IN BURST-MODE SPACE POWER AND POWER CONDITIONING, ON EMERGING SPACE SCIENCE APPLICATIONS, AND ULTRA-HIGH SPEED SUPERCOMPUTING. INTEREST IN SUCH AREAS OF SCIENCE AND TECHNOLOGY CLEARLY ILLUSTRATES THAT SDI HAS GREATLY FACILITATED THE MOBILIZATION OF OUR NATION'S SCIENTIFIC COMMUNITY.

LAST SPRING, THIS OFFICE SPONSORED A REVIEW CONFERENCE FOR UNIVERSITIES. OVER 150 ACADEMIC INSTITUTIONS, REPRESENTING 47 STATES, ATTENDED. SUBJECT AREAS INCLUDED COMPOSITE MATERIALS, ROCKET FUELS, ELECTRONIC MATERIALS, SYSTOLIC ARRAY PROCESSING, SOFTWARE DEVELOPMENT, OPTICAL COMPUTING AND SPACE SCIENCE. SINCE THAT REVIEW, WE HAVE RECEIVED OVER 3700 CREATIVE PROPOSALS FROM AROUND THE COUNTRY FOR THIS PROGRAM--PERHAPS THIS IS THE BEST RESPONSE I CAN GIVE TO THOSE STORIES IN THE MEDIA CONCERNING ACADEMICS AND UNIVERSITY SCIENTISTS WHO CHOOSE NOT TO

WORK ON SDI--AND BOTH EXPECT AND UNFORTUNATELY RECEIVE HEADLINES FOR SUCH A DECISION.

TO BE SPECIFIC, THE IS&T OFFICE IS CHARGED WITH CONDUCTING FUNDAMENTAL RESEARCH PROGRAMS FOR THE SDIO (IN ADDITION TO OTHER MISSIONS). THE POLICY OF THE IS&T OFFICE IS TO STRONGLY SUPPORT, ENCOURAGE, AND FACILITATE INVOLVEMENT IN THE SDIO PROGRAM, FROM ALL SECTORS (SMALL BUSINESS, LARGE INDUSTRY, LABS, AND UNIVERSITIES) WHENEVER THE INTEREST, CAPABILITY, AND GOOD IDEAS EXIST IN THAT COMMUNITY. THE NEEDS OF THE SDIO IN THE AREA OF BASIC RESEARCH ARE COMMUNICATED MOST SPECIFICALLY TO ACADEMIA VIA TECHNICAL CONFERENCES, COMMERCE BUSINESS DAILY ANNOUNCEMENTS, WIDELY DISSEMINATED DOCUMENTATION (THE IS&T BROCHURE) DESCRIBING RESEARCH OPPORTUNITIES, AND DIRECT INTERACTION WITH THE COMMUNITY, SUCH AS PRESENTATIONS TO RESEARCH ADMINISTRATORS (SOCIETY FOR RESEARCH ADMINISTRATORS; NATIONAL COUNCIL FOR THE ADVANCEMENT OF SCIENCE; AND NATIONAL COUNCIL OF UNIVERSITY RESEARCH ADMINISTRATORS) AND REGIONAL UNIVERSITY CONFERENCES ORGANIZED BY THE DOD AND ITS BASIC RESEARCH AGENCIES.

COMPETITIVE PROCUREMENTS ARE FUNDED FOR IS&T PROGRAMS AND PROPOSALS ARE REVIEWED WITHIN THE DOD SCIENTIFIC COMMUNITY. THIS INCLUDES PROGRAM MANAGERS AT THE DOD BASIC RESEARCH AGENCIES AS WELL AS SCIENTIFIC PERSONNEL WITHIN THE DOD LABORATORY STRUCTURE. WHEN REQUIRED AGENCIES OUTSIDE THE DOD, SUCH AS NASA AND DOE ARE ALSO USED IN PROPOSAL REVIEW.

AT THIS POINT IN THE DEVELOPMENT OF THE SDIO, NO DIRECT INVOLVEMENT OF THE RESEARCH PERFORMER IN LONG-RANGE PLANNING FOR THE SDIO MISSION OCCURS HOWEVER, BY THE NATURE OF THE RESULTS OF THEIR RESEARCH, THE PERFORMERS INDIRECTLY DETERMINE THE SCIENTIFIC COURSE WHICH SDIO WILL FOLLOW.

SINCE THE ESSENCE OF THE SDIO MISSION AND GOALS IS INHERENTLY MULTI-DISCIPLINARY, MANY OF THE PROGRAMS MANAGED BY THE SDIO/IS&T OFFICE REFLECT THIS NATURE. RESEARCH CONSORTIA HAVE BEEN ESTABLISHED CONSISTING OF UNIVERSITY, GOVERNMENT LABORATORY, AND INDUSTRIAL RESEARCHERS TO ADDRESS A NUMBER OF THE KEY ISSUES IN THE SDIO PROGRAM PLAN. THESE CONSORTIA MEMBERS BRING A NUMBER OF DIFFERENT SKILLS IN MANY DIFFERENT FIELDS TO BEAR ON IS&T PROBLEMS. AS AN EXAMPLE, IN THE AREA OF SPACE POWER, IS&T HAS SUPPORTED SCIENTISTS SKILLED IN MATERIAL SCIENCES, ELECTRICAL ENGINEERING, CHEMISTRY, AND ELECTRONICS WORKING ON NEW WAYS OF CONDITIONING POWER FOR USE IN HIGH POWER SPACE SYSTEMS. IN SPACE SCIENCE, THERE IS A CONSORTIUM OF SPACE PHYSICISTS, MATERIALS SCIENTISTS, ACCELERATOR PHYSICISTS, ATOMIC PHYSICISTS, AND PARTICLE BEAM RESEARCHERS FROM SEVERAL UNIVERSITIES.

THE INCENTIVES FOR FORMING THE CONSORTIA DESCRIBED ABOVE ARE THE VISIBILITY AND ENHANCED COMPETITIVE STATUS SINCE A CONSORTIUM, IN PRINCIPLE, BRINGS TOGETHER THE BEST TECHNICAL TEAM. IN ADDITION, IT HAS THE ADVANTAGE OF WORKING ON SPONSORED RESEARCH PROGRAMS IN WHICH CLOSE COOPERATION AMONG

INSTITUTIONS IS ENCOURAGED. THE SDIO IS UNIQUE IN THAT THE TRANSITION FROM BASIC RESEARCH TO EXPLORATORY AND ADVANCED DEVELOPMENT IS ACCOMPLISHED WITHIN A SINGLE AGENCY. THUS, THERE IS INCENTIVE FOR INDUSTRIAL RESEARCHERS WHO ARE NATURALLY ATTRACTED TO THE LARGER PROGRAMS ASSOCIATED WITH DEVELOPMENTAL RESEARCH PROGRAMS TO ENTER INTO ACTIVE COLLABORATION WITH ACADEMIC INSTITUTIONS DURING THE BASIC RESEARCH PHASE. THIS WE VIEW AS VERY HEALTHY.

NOW THAT I HAVE DESCRIBED THE MAJOR SDI/UNIVERSITY INVOLVEMENT MECHANISMS, LET ME BRIEFLY SET THE RECORD STRAIGHT ON A COUPLE OF TECHNICALITIES. FIRST, IS&T MONIES AVAILABLE ARE INCLUDED IN A DOD FUNDING CATEGORY LABELED "6.3." NORMALLY 6.3 MONIES ARE NOT USED FOR WHAT THE RESEARCH COMMUNITY CALLS BASIC (UNCLASSIFIED) RESEARCH. HOWEVER, BY DIRECTION OF DR. JAMES IONSON, THE HEAD OF THE IS&T OFFICE, AND WITH THE ENDORSEMENT OF THE DIRECTOR, SDIO, THE IS&T MONIES CONTRACTED TO UNIVERSITIES CAN BE USED AS THOUGH IT WERE FOR FUNDAMENTAL RESEARCH. DR. IONSON'S MEMORANDUM IS INCLUDED AS AN APPENDIX TO THIS TESTIMONY. THIS SHOULD EASE GREATLY THE CONCERN PUT FORTH BY SOME INSTITUTIONS WITH REGARD TO PUBLICATIONS OF THEIR RESEARCH IN THE OPEN LITERATURE.

A SECOND POINT OF CONCERN RAISED BY SOME UNIVERSITY ADMINISTRATORS, WAS, THAT BY ADVERTISING THE AWARDING OF

CONTRACTS TO CONSORTIA OF VARIOUS UNIVERSITY RESEARCHERS, THAT THE SDIO HAD CARELESSLY IMPLIED THAT THE RESPECTIVE UNIVERSITIES THEMSELVES SUPPORTED THE MISSION OF SDIO. I WANT TO STATE CLEARLY, AND FOR THE RECORD, THAT THIS WAS NOT THE INTENT OF THE IS&T OFFICE NOR THE SDIO. WE CONTRACT FOR RESEARCH WORK IN UNIVERSITIES WHERE THE FACULTY HAVE THE ACADEMIC FREEDOM TO PERFORM ANY RESEARCH THEY DESIRE, AS LONG AS IT CONFORMS TO A GIVEN UNIVERSITY'S GUIDELINES THAT INCLUDE SUCH ISSUES AS SAFETY, CLASSIFICATION, AND OF COURSE, QUALITY OF THE RESEARCH PRODUCT. WE DON'T EXPECT NOR WISH TO IMPLY ANY POLITICAL SUPPORT FROM UNIVERSITIES AS INSTITUTIONS. THUS WE WANT TO EMPHASIZE THAT THE IS&T OFFICE HAS ENGAGED SEVERAL CONSORTIA OF UNIVERSITY RESEARCHERS NOT CONSORTIA OF UNIVERSITIES THEMSELVES. IF WE HAVE NOT BEEN CLEAR IN THE PAST, THEN I CAN ASSURE YOU WE WILL BE MORE CLEAR IN THE FUTURE.

SCIENCE AND ENGINEERING INFRASTRUCTURE

IN THE AREA OF THE RELATIONSHIPS OF THE SDIO TO SCIENCE AND ENGINEERING INFRASTRUCTURE, AND PARTICULARLY WITH REGARD TO THE AVAILABILITY OF MANPOWER RESOURCES, I WOULD REFER THE COMMITTEE TO THE TESTIMONY OF COLONEL DONALD I. CARTER, ACTING DEPUTY UNDER SECRETARY OF DEFENSE FOR RESEARCH AND ADVANCED TECHNOLOGY. COLONEL CARTER APPEARED BEFORE YOU ON OCTOBER 2, 1985, AND I BELIEVE DID A VERY COMPLETE JOB OF OUTLINING THE ENTIRE DOD MANPOWER SITUATION. HOWEVER, I DO BRING TO THE COMMITTEE'S ATTENTION THAT THE HOUSE APPROPRIATIONS COMMITTEE TASKED THEIR

OWN INDEPENDENT INVESTIGATION STAFF TO ASSESS THE SDIO MANPOWER RESOURCE REQUIREMENTS. THE REPORT (WHICH IS CLASSIFIED) SHOWED THAT SDIO REQUIREMENTS DO NOT TAX THE AVAILABLE SCIENTIFIC RESOURCES IN THE U.S. EVEN, IN THE MOST AGGRESSIVE OF CIRCUMSTANCES. TO BE SPECIFIC, THE REPORT CITED THE RATIO OF (RESOURCES REQUIRED/RESOURCES AVAILABLE) IN EACH OF THE FOLLOWING AREAS. THESE (UNCLASSIFIED) NUMBERS ARE SHOWN BELOW FOR THE YEAR 1987.

AERONAUTICS & ASTRONAUTICS ENGINEERING	- 3.5%
INDUSTRIAL ENGINEERING	- .5%
CHEMICAL ENGINEERING	- .9%
MATHEMATICS	- .9%
CHEMISTRY	- .2%
MECHANICAL ENGINEERING	- 1%
CIVIL ENGINEERING	- .07%
MATERIALS ENGINEERING	- 4%
COMPUTER SCIENCE	- .6%
OTHER ENGINEERING	- .2%
ELECTRICAL ENGINEERING	- 1.7%
PHYSICIST	-11%

IN A FEW SPECIFIC CASES, SUCH AS OPTICAL SCIENCE, WHERE ONLY TWO UNIVERSITIES IN THE NATION (UNIVERSITY OF ARIZONA AND ROCHESTER UNIVERSITY) PRODUCE PH.D'S, ONE HAS SOME CONCERN. IT IS, HOWEVER, REASONABLE TO ASSUME THAT RESEARCHERS IN

NEIGHBORING DISCIPLINES WILL CROSS-TRAIN AS THE NEED INCREASES. HISTORY HAS CONSISTENTLY PROVEN THIS TO BE THE CASE.

REGULATION DRIVEN RESEARCH

THE SDI PROGRAM IS DRIVEN BY ITS MISSION AND LIMITED BY RESEARCH CAPABILITY AND FUNDING. HOWEVER, SDIO HAS IN THE PAST, AND CONTINUES TO PLAN AND CARRY OUT ITS RESEARCH IN COMPLETE COMPLIANCE WITH THE 1972 ABM TREATY. IN FACT, THE PRESIDENT HAS RECENTLY REEMPHASIZED HIS DESIRE THAT WE USE THE MORE RESTRICTIVE INTERPRETATION OF THE ABM TREATY IN REGARD TO WHAT CONSTITUTES RESEARCH. TREATY COMPLIANT RESEARCH IS WHAT WE ARE COMMITTED TO PERFORM, AND THAT IS EXACTLY WHAT WE ARE DOING.

SDIO AND THE FEDERAL LABORATORIES

FINALLY, A COMMENT OR TWO IS IN ORDER WITH REGARD TO SDIO RELATIONSHIPS WITH THE VARIOUS FEDERAL LABORATORIES. THERE HAS ALWAYS BEEN AND CONTINUES TO BE A NEED FOR NATIONAL LABS TO CARRY ON GOVERNMENT ROLES THAT COMPLEMENT THOSE PLAYED BY INDUSTRY AND UNIVERSITIES. AS RECOMMENDED BY THE FEDERAL LABORATORY REVIEW PANEL IN MAY 1983, WE ARE ASKING THE NATIONAL LABORATORIES TO "PERFORM BASIC AND APPLIED RESEARCH IN AREAS WHERE THE FEDERAL GOVERNMENT HAS A LEGITIMATE RESPONSIBILITY, INCLUDING NUCLEAR ENERGY AND DEVELOPMENT OF MILITARY TECHNOLOGIES AND EQUIPMENT," AS WELL AS "CONDUCT OTHER RESEARCH PROJECTS OF A LONG RANGE NATURE THAT REQUIRE UNIQUE, CAPITAL-INTENSIVE FACILITIES AND MULIPLE DISCIPLINARY APPROACHES."

THIS BRINGS TO A CLOSE MY FORMAL TESTIMONY. I WISH TO AGAIN THANK YOU FOR GIVING ME AN OPPORTUNITY TO APPEAR BEFORE YOU. I HOPE I HAVE GIVEN YOU A NEW UNDERSTANDING OF HOW SDIO IS INNOVATING NOT ONLY IN FINDING NEW TECHNICAL IDEAS, BUT ALSO IN EXPLORING NEW MANAGEMENT MEASURES OF EFFECTIVENESS.

LET ME ADD ONE FINAL STATEMENT THAT APPLIES MORE GENERALLY THAN JUST TO THE ISSUE OF SDI....IN ANY RESEARCH ARENA IT IS ESSENTIAL TO APPROACH THE OVERALL PROGRAM AT ALL TIMES WITH NOT JUST A DEDICATION TO ANSWERING THE QUESTIONS AT HAND BUT ALSO A HEALTHY SKEPTICISM, AS WELL AS WITH CREATIVITY ASSOCIATED WITH THE EXPLORATION OF A NEW FIELD. WITH THE CURRENT PACE OF TECHNOLOGICAL ADVANCEMENT, AND THE STRONG MOTIVATION PROVIDED BY THE HOPE OF A MORE SECURE AND STABLE FUTURE, I BELIEVE THE SDI RESEARCH PROGRAM IS WELL ON ITS WAY.

I WILL BE HAPPY TO ANSWER ANY QUESTIONS YOU MAY HAVE.

SDIO/IST

MEMORANDUM FOR DEPUTY DIRECTOR FOR TECHNOLOGY, DARPA
DEPUTY DIRECTOR OF SCIENCE AND TECHNOLOGY, DNA
STRATEGIC DEFENSE COMMAND PROGRAM MANAGER, OCSA
DIRECTOR, STRATEGIC PROGRAMS, OASN(RE&S)
SPECIAL ASSISTANT FOR SDI, DCS/RDA, HQ USAF

SUBJECT: Reporting the Results of SDIO Sponsored Innovative Science and Technology (IST) Research

The security of the United States depends on an effective defense, of which the Strategic Defense Initiative is a potential future major component. Its ability to cope with future threats depends on how progress is made through Innovative Science and Technology (IST) research. Openness in fundamental research promotes progress toward application of research results.

The conduct and reporting of research performed on university campuses when sponsored by the IST Office of the SDIO, although funded out of budget category 6.3, will be treated as "fundamental research."

Decisions regarding publication of the results of unclassified IST research performed on university campuses will normally be the responsibility of the university author. However, where there is likelihood of disclosing operational capabilities and performance characteristics of planned or developing military systems, or technologies unique and critical to defense programs, the contract will stipulate that the responsibility for the release of information resulting from IST research belongs to the sponsoring office.

NATIONAL SECURITY DECISION
DIRECTIVE 189

NATIONAL POLICY ON THE TRANSFER OF SCIENTIFIC, TECHNICAL AND ENGINEERING INFORMATION

I. PURPOSE

This directive establishes national policy for controlling the flow of science, technology, and engineering information produced in federally-funded fundamental research at colleges, universities, and laboratories. Fundamental research is defined as follows:

> "'Fundamental research' means basic and applied research in science and engineering, the results of which ordinarily are published and shared broadly within the scientific community, as distinguished from proprietary research and from industrial development, design, production, and product utilization, the results of which ordinarily are restricted for proprietary or national security reasons."

II. BACKGROUND

The acquisition of advanced technology from the United States by Eastern Bloc nations for the purpose of enhancing their military capabilities poses a significant threat to our national security. Intelligence studies indicate a small but significant target of the Eastern Bloc intelligence gathering effort is science and engineering research performed at universities and federal laboratories. At the same time, our leadership position in science and technology is an essential element in our economic and physical security. The strength of American science requires a research environment conducive to creativity, an environment in which the free exchange of ideas is a vital component.

In 1982, the Department of Defense and National Science Foundation sponsored a National Academy of Sciences study of the need for controls on scientific information. This study was chaired by Dr. Dale Corson, President Emeritus of Cornell University. It concluded that, while there has been a significant transfer of U.S. technology to the Soviet Union, the transfer has occurred through many routes with universities and open scientific communication of fundamental research being a minor contributor. Yet as the emerging government-university-industry partnership in research activities continues to grow, a more significant problem may well develop.

COPY 5 OF 12 COPIES

III. POLICY

It is the policy of this Administration that, to the maximum extent possible, the products of fundamental research remain unrestricted. It is also the policy of this Administration that, where the national security requires control, the mechanism for control of information generated during federally-funded fundamental research in science, technology and engineering at colleges, universities and laboratories is classification. Each federal government agency is responsible for: a) determining whether classification is appropriate prior to the award of a research grant, contract, or cooperative agreement and, if so, controlling the research results through standard classification procedures; b) periodically reviewing all research grants, contracts, or cooperative agreements for potential classification. No restrictions may be placed upon the conduct or reporting of federally-funded fundamental research that has not received national security classification, except as provided in applicable U.S. Statutes.

Ronald Reagan

COPY 5 OF 12 COPIES

DISCUSSION

Mr. FUQUA. Thank you very much.

We have a vote that just came on. Do you have any questions, Mr. Lujan? I am going to come back and ask some.

Mr. LUJAN [acting chairman]. Just very quickly.

The type of management that you have instituted in SDI with central management and then other people pursuing more—would that work pretty well for other programs?

Dr. YONAS. Well, it is not entirely new. The fact of the matter is that the Department of Energy in working with the national laboratories works in that mode with decentralized execution. To a certain extent, DARPA works with that approach.

It is the idea of having a small group that can provide the priorities, the central direction, and basically try to put the day-to-day decisionmaking in the hands of those people that are closer to the problems and to minimize the superstructure in the Washington arena.

Mr. LUJAN. That is a more efficient way as far as you are concerned to work? I thought that the whole program with DOE and the others was put together really to get away from civil service requirements of people not being able to shift around and to fire them or to bring on new hires. I thought that was the primary purpose of it.

Dr. YONAS. This decentralized execution approach, I think, is a useful way to approach this kind of problem.

Mr. LUJAN. As long as I have the floor, we sometimes get the criticism that you just took over other programs and put them under one heading. Is that partly true, totally true?

Dr. YONAS. Some of the people who are involved in that are aware of the fact that what we did was to take the existing programs, the existing budgets, and bring them together under our framework. But then what we did was to restructure those programs according to priorities that were more in the light of the President's directive. In the process, many of the things that were brought into the program now have been changed drastically and are moving off in new directions.

So, I think the program is a very different program than the program that we inherited that existed before the formation of the SDI.

Mr. LUJAN. Most of those programs that you brought in were defense related anyway?

Dr. YONAS. They were certainly related to the SDI mission, but they were structured in ways that didn't have this kind of direct and specific goal orientation.

Mr. LUJAN. What I am getting at is, those programs that you brought in under the umbrella of SDI, were a great number of them considered by researchers, university researchers in particular, as nondefense related? I am trying to get at this whole argument that——

Dr. YONAS. No, these programs really didn't bring in university programs under our wing. What we are trying to do is to create new university programs that didn't exist through this innovative science and technology.

Mr. LUJAN. So, what we hear——

Dr. YONAS. I think we are creating new opportunities for universities to exercise their creativity in attacking these new and very challenging initiatives.

Mr. LUJAN. You have 5 percent as being the university percent.

Dr. YONAS. That was in 1985.

Mr. LUJAN. Didn't we hear yesterday that DOD has about 12 percent?

Dr. YONAS. I don't know. That could be overall.

Mr. LUJAN. Overall, yes, basic.

Dr. YONAS. Yes, I think our basic research is again in the 5-percent range, maybe a bit less than that.

Mr. LUJAN. I am going to go over and catch that vote, and we will be back.

[Short recess taken.]

Mr. FUQUA. I apologize for the interruption, but we had a big matter to take care of over on the floor, that of approving the Journal of yesterday.

Dr. Yonas, are there any current Federal personnel policies that you see that are hampering your organization's ability to recruit competent personnel?

Dr. YONAS. I think it is well known that the Government has a difficult time competing with the private sector in terms of salaries. I am not sure I know what to do about that. It is a fact of life.

Engineering and scientific personnel have a difficult time in terms of competitive salary situations, but the overall Federal restrictions on salary ceilings are a reality.

Mr. FUQUA. Most of the people that are working in your organization, you are not doing—I gather from the figures you gave us—you are not doing any research in-house? Most of it is contracted out, 75 percent to industry, 20 percent to the Federal labs, and 5 percent to the universities, I believe.

Dr. YONAS. Right. There is no SDI house. There is no SDI laboratory or institution in which we could pursue research independently.

Mr. FUQUA. How do you choose which organization receives funding? Do you have an in-house or peer review process? How are those projects evaluated to determine how you get the best science or best research?

Dr. YONAS. The review process has many different forms. I mentioned in the Innovative Science and Technology Program—or I may not have mentioned in my oral testimony—that the program is managed—the hands-on management is carried out by research agencies within the Services and that the management is carried out by Government scientific and engineering personnel within these agencies or within the DOD laboratories. In that case, the management decisions in terms of deciding who is funded are made primarily by those Government personnel. They do not carry out a peer review process. They occasionally go out to other agencies such as NASA or DOE to again use Government personnel for that review process.

Within the other program elements—and some of these program elements involve fairly large programs—what we normally do is advertise. We advertise and request proposals. These proposals are

then reviewed by panels of Government officials. Depending on the size and the nature of the procurement, it could be a fairly extensive review process.

Mr. FUQUA. When you say you advertise, is that like in Commerce Business Daily?

Dr. YONAS. Commerce Business Daily. After proposals are received and we go through a governmental review process, we award contracts to, in some cases, multiple bidders and, in some cases, a single bidder.

So, for most of our contracts, it is a fairly typical process of advertising and receiving proposals and proposal review and then award.

Mr. FUQUA. You had a breakdown of manpower requirements. What disciplines do you generally support in your organization or does it generally follow this on page—oh, there is not a page number.

Dr. YONAS. Yes. That listing is the listing from the House Appropriations Committee special investigative group that looked at the manpower requirements. What they in fact found out is that this program touches every discipline. We are not interested in biological sciences, but basically this really touches all the areas of science and engineering that are current and covers such an enormously wide range that we are relying on practically all aspects of the technical community.

Mr. FUQUA. This generally based on the manpower needs would say that you have 11 percent for physics and 1 percent for electrical engineering. Would that about break down as to how your—in other words, physics would probably be the largest area that you——

Dr. YONAS. No. That reflects the fraction of the available resource. That was the estimate of that committee. It says that of the available resource out there, we will need that portion of that in fiscal year 1987, but in terms of the actual break down, in terms of our own relationship within that, that would be a different set of numbers, and I don't have that.

Mr. FUQUA. I realize that, but I mean would it mean that physics would probably be the highest area rather than something like—you have almost 1 percent for mathematics. That is an 11 to 1 ratio. Your major emphasis would probably be in physics, I imagine.

Dr. YONAS. Well, it is certainly true that physics is an important aspect of our program, but engineering, advanced engineering disciplines and materials research, electronics, computer hardware and computer software—and there are many cross disciplines at this point which are the result of the combination of science and engineering disciplines. For instance, optics, advanced optical techniques involve at this time nonlinear processes, not just the classical optics approaches but require the involvement of everything from atomic physics to electronics.

Mr. FUQUA. You referred to Dr. Ionson's memorandum which stated that university research on SDIO topics funded through the Office of Innovative Science and Technology will not be classified. My question is what legal authority does Dr. Ionson or SDIO have

to make such a claim? If you do, is it just consistent with the National Security Directive 189 of September of this year?

Dr. YONAS. I think within the SDIO, the Director, General Abrahamson, has the ultimate authority to decide how to distribute funds and how to define areas of research. It is my impression—I am not an expert legal authority in regard to this kind of program—but it is my impression that General Abrahamson has the authority to make that kind of determination as long as it is consistent with other statutes. In fact, it is our determination that it is consistent with the National Security Directive which defines fundamental research and defines how fundamental research will be managed.

Mr. FUQUA. Mr. Brown?

Mr. BROWN. Mr. Chairman, I don't have any questions at this time. I am certainly glad Dr. Yonas can be here with us today.

Mr. FUQUA. Thank you very much, Dr. Yonas. We appreciate your being with us.

Dr. YONAS. Thank you.

Mr. FUQUA. Our next witness will be Dr. Robert S. Cooper. He is the former Director of the Defense Advanced Research Projects Agency and now in private enterprise with Pollard Road Inc.

It is good to have you with us.

[A biographical sketch of Dr. Cooper follows:]

DR. ROBERT S. COOPER

Dr. Cooper is President, Chief Executive Officer and Chairman of the Board of Directors of Pollard Road Incorporated. PRI is a new startup company devoted to serving the defense electronics market. Its products and services will span the spectrum of defense needs in surveillance and countermeasures and employ advanced technology in the areas of electronics, electrooptics, advanced computers, signal processing and artificial intelligence applications.

From 1981 to 1985, Dr. Cooper was Assistant Secretary of Defense for Research and Technology and simultaneously held the position of Director of the Defense Advanced Research Projects Agency. As Assistant Secretary, he was the principal advisor to the Secretary of Defense on the allocation of Department resources to research, exploratory development and advanced development projects. He has established Defense policies, program priorities and directed actions of the Army, Navy, Air Force and Defense Agencies to assure future technical preeminence of U.S. weapon systems.

In his role as Director of DARPA, Dr. Cooper directed the technical activities of one of the foremost advanced research and the development organizations in the world. Under his direction during the past four years, the Agency has produced major accomplishments and started new R&D programs in such diverse areas as strategic defense, advanced aeronautical systems, gallium arsenide microelectronic circuits, advanced surveillance sensors, terminal homing sensors, and new generation computing technology employing artificial intelligence concepts. DARPA under Dr. Cooper's direction had a strong influence on the Nation's technical future through leveraged investments in promising high risk, high payoff research projects. DARPA's total annual expenditures are at the $800 million level.

Prior to joining the senior Defense research management team under Secretary Weinberger in 1981, Dr. Cooper was Engineering Vice President of Satellite Business Systems. In this firm, he was responsible for the development, integration, installation and testing of an advanced spread spectrum digital communication satellite system which was completed and brought to initial operation serving the first three customers within three years.

Prior to joining SBS, Dr. Cooper held a variety of R&D management and engineering staff positions. Among these were Director, NASA Goddard Space Flight Center, Assistant Director of Defense Research and Staff Member, Group Leader, and Division Director at MIT's Lincoln Laboratory.

Dr. Cooper holds a Doctor of Science degree from the Massachusetts Institute of Technology in Electrical Engineering and Mathematics.

STATEMENT OF DR. ROBERT S. COOPER, PRESIDENT, POLLARD ROAD INC., ARLINGTON, VA; AND FORMER ASSISTANT SECRETARY OF DEFENSE FOR RESEARCH AND TECHNOLOGY, AND DIRECTOR, DEFENSE ADVANCED RESEARCH PROJECTS AGENCY, U.S. DEPARTMENT OF DEFENSE

Dr. COOPER. Thank you very much. I am pleased to be here to discuss this very important issue with the committee.

I would like to submit my formal statement for the record and——

Mr. FUQUA. Yes, we will permit that, and if you wish to summarize, it will be fine.

Dr. COOPER. During the past 4 years, I have been involved, as you pointed out, as the Director of Defense Advanced Research Projects Agency, but I have also held the position of Assistant Secretary of Defense for Research and Technology which placed me in the highest councils of the Defense Department in the setting of research policy. I would like to share with you some of the views that I have come to hold over these last four years on some important issues.

Your committee is considering research and development in the United States and without closely scrutinizing what the Defense Department does in this area, you certainly would have a very restricted picture of what is going on because the Government today funds about 50 percent of the research and development activities in the United States with the industry carrying the preponderance of the rest of that burden. Of the 50 percent in the Government, 60 percent of that total resides in the Defense Department. So, Defense is essentially a preponderant funder of R&D in the United States. Therefore, any policies that are set within the Department of Defense certainly have ramifications into almost every part of our society.

I have had an unusual opportunity during my career to look at this relationship between Government and the scientific and engineering community from just about every imaginable aspect. I have been in the academic community for quite a number of years. I was associated with the Defense Department in the early 1970's. I was Director of one of NASA's large space flight centers for a number of years, and I have been in private business and been back again into the Government and in on some of the most important decisions that have been made for defense research over the past few years.

Over that period of time, I have formed some very strong opinions about some of the problems in relationships that exist particularly between the Defense Department and the scientific and engineering community.

When you are looking at R&D policy, you are really looking at a very nebulous and diffuse thing. Most of the people who come to Washington believe that they are setting policy. Congress certainly believes that it does. Folks in the White House do. Congressional staff think that they really are the ones who set policy in the country on every issue and science and engineering are no exception.

So, it is really hard to find out who the people are who actually set Government science policy. The conventional wisdom, of course, in this city, is that as far as policy setting goes, it is done essential-

ly by those people who disburse funds, those people who have the Government's money in their control and can lay it on the line. They characterize that as the golden rule, that is, he who has the gold rules.

I think there is a misapprehension on the part of most people in power in the city that policy really is the disbursement of the funds, but there are many, many issues with regard to setting policies that are much more important than the money in determining what is happening over the coming decades in the science business. I would like to, in the balance of my discussion here, focus some attention on some of those issues which I think are very important.

In order to put things in context as far as defense is concerned, defense R&D expenditures in the President's request and what the Congress has before it now in the 1986 budget year represents about $31.5 billion. Of that $31.5 billion for R&D, very little of it is for R and lots of it is for D. In particular, two-thirds of those funds lie in accounts that are essentially doing engineering design and development of systems. There is little research per se that is funded by those moneys. In particular, they have little impact on the research community which is interested more in basic and applied research at the fundamental level.

However, one-third of those moneys lie in three accounts which you should focus your attention on and which are important. They are the so-called basic research account, the exploratory development account, and then another piece of a third account called advanced technology demonstration. In Defense parlance, those are 6.3a funds to be distinguished from 6.3b funds.

The total of those three accounts is about $9 billion in the President's request for 1986, and some substantial fraction of that $9 billion actually impacts the research community in our universities, in our industrial laboratories, in the Federal laboratories, and in small business.

It is hard to say exactly how much because there is no fine line of demarcation between basic research and fundamental applied research and the more development activities that follow, but for purposes of categorization, the Defense Department places that line at 6.3a, and the 6.3a funds are really meant to be transition funds that allow us to take both basic and applied research activities that are maturing and to place them into a position where an engineer could actually engineer something that could be useful to society using the basic and applied research results.

With those categorizations, it is my feeling that probably Defense spends about half of the total funds that the Government spends on research that impacts basic and applied activities up through the technology transition phase. This is true for all of the mission agencies, for Defense, for Energy, for NASA, for all of those that have both basic and applied research activities ongoing.

As far as setting policies in the Defense Department goes, of course, the Secretary of Defense is authoritative on that, but he has a principal advisor, the Under Secretary for Research and Engineering who has a great deal of influence on that process. The R&E Under Secretary relies on a number of other people. Recently, this new position that I held over the last 4 years of Assistant Secretary for R&T was created to oversee the activities in those three

accounts and to help both the Under Secretary and the Secretary of Defense make decisions about how those funds would be spent, and what some of the other policies were that were set in the Defense Department in order to help guide the management and disbursement of those funds or the execution of the research programs funded by those monies.

On the other hand, there are many other people who play in that game, the Assistant Secretaries for R&D and Acquisition in the military departments, the military chiefs of R&D. There are a number of folks on the R&E staff who help support the Under Secretary. Of course, the comptroller and the program analysis folks in that office also have a great influence on the Secretary about setting such policies.

So, it really is hard to tell how the policies get set. As a matter of fact, it is my experience over the past 4 years that essentially policies are set by the strong interpersonal relationships that exist among those high level officials. Issues are brought up. They are decided. Various people take various positions on them, and then they interact strongly at both the management and the personal level until a consensus is formed and then the Secretary is given advice. He acts on that advice when there is a decision memorandum in front of him, and he depends on his personal relations with these people in order to decide what the final policies will be.

That process is one that is highly personal. It probably is not amenable to any substantial change. It is a matter of style with the individual Secretary and the way he operates. It has changed many times throughout the years as the various administrations and Secretaries have changed. I have seen that process now since the 1960's in four or five different administrations, both from close at hand and from afar. I can say that it works pretty well or it has worked pretty well in almost all of those settings.

There are some things which have been happening over the years which are trends which are strongly affecting Defense's ability to prosecute research in a way that is beneficial to the United States. I would like to turn now to four key issues and just mention briefly some of the problems associated with Defense research activities.

Those four issues deal, interestingly enough, not so much with the content of research or the programs or the people particularly at high levels who are making decisions, but they deal with more mundane things such as research contracting regulations and the effect that it is having on our ability to get research done; personnel policies which you have brought up in previous questioning; internal management practices which have slowly grown up over the years and seem to be immutably moving in the direction of less and less flexibility, more rigidity and less ability to make reasonable decisions; and, finally, the whole issue of information security regulations or policies which are having a very chilling effect now on our relations with the scientific and engineering community.

First, research contracting. What is the problem? Well, the problem is that the attitude that the Congress has taken and the attitude that the Defense Department has taken toward contract research and contracting in general has resulted in an increasing mountain of laws and regulations which prevent the easy connec-

tion between people in Government and people in the scientific and engineering community to set research projects in motion, to get them moving, and to get the research done.

It is my view that this problem now ranks as the number one deterrent to getting our dollar's worth out of defense research moneys that are expended in the basic and applied research areas. It is an aggravation both to the program managers in the Defense Department and to the researchers themselves, and it is causing a great deal of consternation in both camps and a good deal of ill will and animosity between the two groups.

Let me say that viewing that from the perspective of the 1960's when I first got into the research business after having graduated from MIT, I can say that was not the case in the early 1960's. There was a very close relationship between people in Government and people in the research and development community, and they were able to work together both before, during, and after the contracting process. We were able to get an enormous amount done during that period of time. The other mission agencies such as NASA and, at that time, the Atomic Energy Commission and others also benefited from this free association and relationship between Government managers and scientific researchers.

More and more, the Defense Department and the Government in general has placed the procurement restrictions that we like to place on the acquisition of large systems to ensure the procurement integrity onto the relationship between an individual research worker, say, in a university or in an industrial scientific laboratory and his Government counterpart with whom he is trying to do business and to make decisions. That process really has been a very immutable process down through the years, and it has come to the point now where it can take as long as 1 year to get a research worker under contract even after a Government worker and a research worker have agreed on what the research should be, and there is an enormous amount of paperwork burden on both sides. Lost effort in the Government; lost effort on the research project, wasted money essentially.

Personnel policy. Well, all of the mission agencies now suffer from the fact that the individual managers in the organizations that manage Government research are of increasingly inferior quality as time wears on. This fact is due to the fact it is very difficult to both get into the Government to help the Government out for a short period of time and get out.

It is probably most important to the mission agencies that they have access to the scientific community, to bring them into the Government for short periods of time and to get them out. The reason for that is the reason that you were getting at in your discussions with Dr. Yonas. That is that the decisions on what research gets done and who does it are really the policy issues that make for quality science in the United States.

That process is different in the mission agencies than it is in the National Science Foundation and the National Institutes of Health. In those organizations, the workers in Government are mainly paper shufflers. They sit and wait for the research proposals to come in. They shuffle them into piles, and then they shuffle them out to peer review groups who are really the research workers

themselves, and they ask for them to grade them and to send them back and tell them which ones to fund. When they come back, they organize the ones that are funded in one pile and the ones that are not funded in another pile. They go into the wastebasket. The ones that are funded go to the contracting organization and the contracts or the grants are set, and the process is complete.

There is some but probably not a great deal of insight that needs to be put into the system by the people in Government. It is all regulated by the scientific community itself.

We attempt to emulate that process in some way in the mission agencies, particularly in NASA in the scientific parts of NASA. However, by and large, the decisions on who does the research and what research gets done are decisions that are taken by people in Government. In order to ensure that that process is a quality process, the people have to be quality people.

Currently, the Government is not competing for quality people, and it has no way to compete for quality people with our current personnel policies. In my paper, I have made a number of suggestions as to what I believe needs to be done in order to fix that problem so that we can begin to get quality people back into Government to make the essential decisions.

Management practices. Basic research and exploratory development in defense are processes of discovery, that is, research projects are started on speculation and we don't know really where they are going to go. As the research continues, new things come up. New opportunities arise, opportunities to increase the activity in a particular area to take advantage of an opportunity or to perhaps change direction. Those opportunities all require discretionary funds.

The Congress' attitude about discretionary research funds, that is, setting aside reserves that can be used during the budget year to be able to pounce on opportunities and to move research in the right direction has increasingly been one of not allowing such things. Also, the management in the mission agencies has responded to that by both not allowing their individual managers to hold back reserves for taking advantage of tactical situations during the budget year and searching for the places where they tried to hide such funds so that that can be done.

So, increasingly, I have found over the past 4 years in looking at the way defense research funds are managed in all of the military departments and the defense agencies that there is less and less and less flexibility to take advantage of opportunities in research and that more and more and more of the programming, planning, and budgeting cycle which now lasts at least 3 years—that is, you are both considering the current year, the next budget year, and the budget year beyond that—that funds tend to get locked up or locked into what may be low payoff of diminishing return areas rather than being available for rapid change.

I think we need to change that process. In my paper, I have made a number of suggestions which I think should be implemented.

Principal among those suggestions is a suggestion on the issue of the 6.3a funds, the transition funds which are set aside in defense to try to transition technology from the laboratory into our sys-

tems. It is my belief that the United States today is going through a crisis of transition of technology, not only in defense but in our industries as well. We are noncompetitive in many areas of research and development because of the fact that we haven't paid attention to the process of technology transition.

How do you determine, how do you set aside resources for, how do you focus both management's attention and research workers' attention on this whole process of transition?

The fact is you can't if you don't try, and we don't. The Japanese, the Germans, the Soviet Union do focus attention on that. They do try, and, increasingly, they are beating our pants off not only in the defense sector but in the commercial developments as well. I think we just have to pay more attention to that.

A trend that has occurred in defense is a trend that started in the late 1960's when the 6.3a account was set up. This is the technology transition account, and it has a substantial amount of money in it. It is upwards of $1 billion today. It was meant to demonstrate technology on some grand scale, to aggregate technologies, and to make leaps forward by building experimental aircraft, building experimental tanks, building experimental accelerators or experimental satellites that have the newest technology in them. They are not meant to be a prototype of any weapons system or any other useful system but only to bring the maturity of the technology up to where it could be used in an engineering design of some system or some concept in the future.

That account was set aside for that. Initially, it was used for that. As a matter of fact, the F-16 fighter plane came out of that funding account, and the concept of a technology transition or experimental platform. So did such concepts as the hydrofoil and the air cushion ship vehicles. Some of those didn't pan out and were never used on any substantial scale, but the F-16 is an example of how that kind of paying attention to transition of technology can really pay off.

But quickly the bureaucracy over in Defense found these funds and began using them for a number of purposes for which they were not meant. Those funds today by and large now are used to support very small and insignificant, in my view, research projects mainly to support the defense laboratories.

The account is also used as a slush fund to fund overruns in 6.3b which are the beginnings, prototypes, of engineering developments or system developments. That is very nice, because being in the 6.3 account, you can move funds through that 6.3a/6.3b barrier without the Congress seeing you do it and even without the senior management, particularly the Assistant Secretary for Research and Technology seeing you do it in the Defense Department.

To counter that, the Under Secretary for Research and Engineering in the Carter administration, Bill Perry, began to set aside funds in the Defense Advanced Research Projects Agency for significant technology transition projects. In particular, the Stealth technology that the country now is developing and is moving into systems very rapidly was developed because that technology was transitioned using DARPA funds on a substantial scale.

There are many other examples now of programs that DARPA has that are technology transition programs, and DARPA has es-

sentially taken on the burden in the Defense Department of trying to develop leap-frog capability and to demonstrate it at large scale. It is a process or a task that DARPA was not intended to do, but they are doing it by default.

That is why my recommendation is that we set up in the Defense Department—and I have been working for that over the last 4 years to essentially no avail—an organization whose specific responsibility is to use the 6.3a funds to fund experimental vehicles and techniques at a substantial scale to transition technology out of our research laboratories and into our systems.

Finally, there have been proposals in the Secretary's staff over the last few years which have had a very chilling effect on our relations with the scientific community. These are proposals to have prior review of scientific and engineering results funded in our basic research programs before publication.

It is true that we do have a serious problem protecting technical information and products in defense from our adversaries, particularly since they have stepped up their activity over the past few years enormously to try to get scientific and engineering results and products out of the United States and to use them in developments of weapons systems in the Warsaw Pact nations.

On the other hand, I believe that our tones have been too strident in defense. I believe it is time for us now to project a sense of reasonableness and compromise on this issue to the research community, and to try to draw them into the interpretation of what the national interest really is in the national security sector and to bring them into the process of determining what facts should be protected, what information should be protected, and what products should be protected, and exactly how to do that and not violate the principles of the free flow of information in basic research and applied research at the fundamental level. It is very important to maintain that principle, by the way, because it is that principle, I believe, which is the strength of that entire area.

I just wanted to end on a note. DARPA, the Defense Advanced Research Projects Agency, is a unique organization, and I have really been honored to be associated with it over the past 4 years, and I left it and the Secretary's office with mixed emotions for that reason. DARPA was created at the time the Sputnik was launched by the Soviet Union, and it was set up in order to keep the Defense Department and the Nation at the forefront of technology.

I think that the concept of DARPA is perfect. It is a small organization, a scant 150 people. It has a budget of near $1 billion. It is dynamic. It is close to the Secretary. There is no question about where the authority and responsibility for the decisions about what to do with that research money lies; it lies directly with the Director. There is approval that comes from the Secretary's office, but, by and large, he is very liberal and does concentrate the authority and responsibility for decisions there.

Consequently, DARPA has been able to make contributions in every decade that are at the highest level. We would not have a strategic defense program today if it hadn't been for the development of the technologies that are in that area in DARPA over the last 10 years. We would not have and would not be competitive in the world community in computer science and computer technolo-

gy, probably not even in microelectronics technology if it hadn't been for research accomplished at DARPA. Certainly, in the national security area, such developments as stealth technology, surveillance technology which guards our national interest in many, many ways clearly would not be where they are today without DARPA.

But I must say that DARPA is beginning to suffer even though it is so closely connected to the Secretary and has had an ability to cut through the bureaucratic redtape in the past. It is having a great deal of difficulty right now from the issues that I brought up before.

The contracting issues are making it almost impossible for DARPA to maintain its contacts with the scientific and engineering community as it has in the past. These contract barriers are artificial. They are things that we have created for ourselves. We can ensure the integrity of the research contracting process without putting in year delays and all of the consternation and frustration that goes along with all of the paper that is generated in that process.

We are an information society. We are electronic. Why can't we eliminate the paper completely and go to computer communications with the scientific community completely? DARPA has set the stage for that by creating ARPANET, and we do communicate with the scientific community. There is no reason why we can't do our business in that way as well.

DARPA has an enormous reputation in the scientific community, a very strong reputation for quality research management in Government, and we have been able to attract into DARPA some of the best and finest scientific and engineering people available. But in the last 5 years, I have had a continuing difficult time bringing high quality people into DARPA.

One of the other reasons why DARPA is so great is that it is not an institution. It supports no institutions. It has about 80 to 90 scientists and engineers on the staff, and those turn over at the rate of 25 percent a year. That is, the whole organization changes every 4 years. So, its vitality is assured.

There is no corporate memory at DARPA. Beyond 7 or 8 years, no one even remembers what DARPA did. There is no one there who was there at that time. Consequently, it gets revitalized.

If we stop that revitalization process by making it impossible to bring young, dynamic, and the best scientific and engineering minds into that organization, then it will no longer be able to serve the national interest the way it has in the past. I really think we must do something about that. It is a serious problem.

Also, the relationship with the scientific community is one based on trust and mutual respect. Certainly, a recognition of the external threat that DARPA was intended to counter with its advanced technology, the scientific community has respected that down through the years. To place undue restrictions on the flow of scientific information generated in DARPA programs when it is not needed but to ensure that it does occur when it is needed is a process that we have always been able to manage by personal relations with the scientific community. These recent proposals to make restrictions on the scientific community have even begun to affect

the relationship between DARPA and the scientific community which has always been very good.

I appreciate the opportunity to come and talk to you about some of these issues. I would be willing to answer any questions you have either about DARPA, about the setting of science policy as I see it in the Defense Department, or any other aspects of the research community and government relationship that I can help you on.

[The prepared statement of Dr. Cooper follows:]

BEFORE THE

SCIENCE POLICY TASK FORCE

U.S. HOUSE OF REPRESENTATIVES

COMMITTEE ON SCIENCE & TECHNOLOGY

CHAIRMAN, HONORABLE DON FUQUA

STATEMENT

BY

DR. ROBERT S. COOPER

PRESIDENT, POLLARD ROAD, INC.

FORMERLY:

ASST. SEC. OF DEFENSE AND

DIRECTOR, DEFENSE ADVANCED RESEARCH PROJECTS AGENCY

OCTOBER 23, 1985

Mr. Chairman, I am pleased to appear before this committee to give you my views on Defense basic and applied research policies. I agree with the aims of this Committee and those of the Science Policy Task Force to better understand the rationale and mechanisms for federal support of research. Since the federal government funds nearly 50% of all R&D in the United States and the Defense Department's share of that support comprises over 60% of the government total, Defense policies in the R&D sector have a powerful influence on the direction of science and technology in this country. Because it is the nature of the results of research that they impact every facet of this complex technological society, Defense research not only impacts our national security but has ramifications for the nation's overall economic well-being as well. Therefore, without a full review of Defense research policies you would have only a partial picture of the forces which shape R&D in the U.S. and will affect the future of each of its citizens.

My entire career has been spent in research and development during my years on the faculty at M.I.T., my tenure at M.I.T. Lincoln Laboratory, my tour on the Research and Engineering staff in the Pentagon, my years as Director of NASA's Goddard Space-flight Center, my industrial experience as Engineering Vice President at Satellite Business Systems and recently as Assistant Secretary of Defense and Director of DARPA. I have been privileged to work with some of the finest scientific and engineering minds in the Nation, and I have viewed the changing relationship

of the technical community with its government mentors from every aspect. Because of these experiences I have formed strong opinions about how the government interacts with the research community; what is right with the relationship; what is wrong with it and how to fix the problems. I would like to share some of these opinions with you, focussing particularly on the Defense Department.

Defense Research Policy Formulation

Government R&D policy is not a single "entity" but is rather a complex aggregation of law, regulations, practices and individual decisions created by literally thousands of people mainly inside of government. Understanding who these people are and how they influence the research policy-making process is a truly daunting task. Defense research policy is no exception.

Government's attitude toward research is certainly set by the President and the White House science policy infrastructure. However, the Congress, the administrators of the major funding agencies such as NSF, Energy Department, Defense Department and NASA all play major roles. Even personnel policies set by the Office of Personnel Management are very influential in the outcome of government attitudes toward research. I will say more about this later.

Conventional wisdom in Washington is that policy is actually set by those who disburse research funds at the working level.

In my view this belief is erroneous because many other factors have an equal or even greater influence on research directions. However, on this basis Defense would be the most influential determiner of basic and applied research policy in government. This is true even when one discounts the engineering development funds related to specific weapon system developments which cannot really be classified as either basic research or applied research. Instead, those funds, which comprise two-thirds of the Defense R&D budget, should be thought of as applied to equipment design. Nevertheless, the FY86 Defense budget request for funds in the Basic Research, Exploratory Development and Advanced Technology Demonstration accounts total $8.986 Billion. This total probably equals the sum of all other comparable federal investments in basic and applied research exclusive of Health and Human Services (National Institutes of Health).

Persons who are most influential in determining how these funds are allocated and expended are the Secretary of Defense and his principal staff advisor on R&D who is the Undersecretary of Defense for Research and Engineering. In recent years a new position was created on the Secretary's staff specifically to provide additional oversight and advice to the Secretary on fund allocations to these three accounts. That position was designated Assistant Secretary of Defense for Research and Technology. Others in the Department who have some influence on both funding and other factors influencing the direction of Defense research are the civilian Assistant Secretaries for R&D

in the military departments, the military R&D chiefs, the heads of certain of the Defense Agencies, the Director of the Strategic Defense Initiative Organization and more recently certain members of the Defense Security staff. Program Analysis and the Comptroller play a major role in attempting to curb the apparently insatiable appetite for funds of the basic and applied research programs.

By and large the process by which Defense research funding policy is set and carried out is a function of the complex interpersonal dynamics of this relatively small group of people and their advisors.

Key Defense Research Policy Issues

Despite the misconception that funding is the principal means of setting research policy, there are four policy issues which today are much more important and limiting on Defense in realizing its long term research objectives than funding.

In order of importance they are:

1. Research Contracting Regulations
2. Personnel policies
3. Internal management practices, and
4. Information security policies.

Research Contracting

Resent changes to government procurement laws and the resulting Federal Acquisition Regulations (FAR) as well as the corresponding Defense Acquisition Regulations (DAR) have made contracting for Basic Research and Exploratory Development with both universities and private firms into a nightmare. This problem now ranks as the number one deterrent to efficient and timely development of new and innovative research efforts applied to Defense problems. It is a prime aggravation both to government program managers and to researchers and is creating consternation and ill will between them.

The prime factors are 1) procurement leadtimes, which have grown from about 90 days on average to as much as 285 days from research proposal submission to contract signing, and 2) the exorbitant amount of paperwork required for proposal submission and reporting of research progress as well as the arms-length relationship which is imposed on the parties involved. These detrimental factors result mainly from an insistence by the Congress and by Defense acquisition management that research contracting be subjected to the same formalized process by which major weapon systems and general military supplies are procured. That formal process was constructed to insure procurement integrity and competition in contracting. It does not recognize the special nature of research contracting nor the need both for

brevity in the process and a close communication between technical management in the government and the research worker before, during and after the contracting process. If there were only one aspect of Defense research which I could change to improve it, it would be to change the rules by which research contracts are secured. I believe the following steps are appropriate:

1. Change the laws and regulations controlling Defense research contracting. Give it a special status and recognize its special needs.

2. Reduce procurement lead times to 90 days maximum for contracts less than $2M and 150 days for those between $2M and $10M.

3. Accept abbreviated proposals and minimize required "boiler plate" appendixes to both proposals and contracts governing small scale research ((($2M).

4. Accept the concept of "competition of ideas" as satisfying the government-wide goal of providing competition in contracting. Do not require, as a management practice, that any fixed percentage of research contracts be "competed" in the formal sense of the word but instead recognize the processes by which

unsolicited proposals and sole source awards are made as legitimately satisfying the "competition" requirement.

5. Simplify the reporting requirements for basic research, and

6. Streamline financial audit procedures for small businesses and universities as they relate to basic research and exploratory development contracts.

Personnel Policy

The government, particularly Defense, needs competent, experienced, bench level, middle management level and senior scientists and engineers to help manage its research business. Short term, 3 to 4 years, non-career appointments of highly competent people to key government jobs should be made easy to accomplish. Current personnel policies make special arrangements of this sort virtually impossible. Moreover the financial sacrifices required of individuals with highly marketable scientific and engineering skills to serve, even for these short periods, are completely unreasonable. We should take the following steps to fix this problem.

1. Set up a special, limited term, government employment policy for scientists and engineers (similar to but more liberal than the old PL-313 status).

2. Set up a compensation plan for these appointments which substantially matches their civilian compensation. Perhaps this could be done through contracts with their parent organizations.

3. Delegate selection and other decision making relating to the terms and conditions for these appointments to line management. Give them flexibility to compete for the best and finest. Relegate the Personnel Management bure&ucracy to a support role in these special categories of hiring.

4. Limit the leadtime for this type of hiring to a maximum of 3 months.

5. Liberalize the conflict of interest statutes in relation to these special employees.

A personnel policy of this sort would do more to upgrade the quality of Defense laboratories than any other single action the government could take.

The reason why this issue is so important for Defense is that virtually all research is arranged by contract and the selection of individual research workers to carry out the contract research work is made by government scientist and engineers. The quality of the product is entirely dependent on the selection process and without technically competent government personnel to administer this process, there is little chance of achieving a quality product. We must find better ways to attract the best and brightest people from the research community into government for short (3 to 4 year) tours of duty.

Management Practices

Basic research and exploratory development are processes of discovery. To be successful, discretionary resources must be available during the budget year to make possible an increase of tempo or a change in direction as new discoveries are made. The cumbersome process of programming, planning and budgeting which is now uniformly applied across all R&D is inappropriate for more basic research. Also, the long approval chain required by the military departments for program changes and the management systems intolerance of opportunity reserves within the budget must be changed. The following changes in management practices would help:

1. Further decentralize the management of research funds making the offices of scientific research in the

military departments less dependent on headquarters staff for detailed approvals.

2. Consider setting up small highly capable technical management organizations for the Advanced Technology Demonstration (6.3A) accounts in each service.

3. Set a goal of 10% opportunity reserve in the research and exploratory development accounts at the beginning of the budget year and protect these reserves from raids by headquarters staff throughout the year.

4. Further streamline the programming, planning and budgeting approval process for research and exploratory development programs.

Of course these measures can be successful only if the scientific quality of the personnel in the field organizations administering the funds is significantly improved.

Information Security

Defense has a serious problem protecting technical information and technical products it provides for itself in the R&D program from being acquired illegally by the Nations' enemies. This is particularly true in the light of recent increased and organized efforts by the Warsaw Pact nations to

target specific high technology products in this country for illegal acquisition. Proposals by the Security Policy staff in the Secretary of Defense's office to require prior review of research results before publication have had an extremely chilling effect on relations between the scientific community and Defense.

Although the concerns for security are legitimate and require stepped up measures for protection, means must be found to protect the Nation's interests while accommodating the free flow of basic research and most exploratory development information. To set the research community at ease, I believe that, as a minimum, we should:

1. Reaffirm the current policy of exempting all basic research results from prior approval.

2. Return the responsibility for detailed review of exploratory development results to the Research and Engineering staff.

3. Delegate review of exploratory development results with broad guidelines to technical program monitors in the field and involve the R&E staff on an exception basis.

4. Project a sense of reasonableness and compromise on this issue to the research community while sensitizing

them to the need for them to become involved in interpreting and protecting the national interest in this area.

Defense Advanced Research Projects Agency (DARPA)

DARPA is a unique and valuable asset to the Defense Department and this country. It was created by Public Law at the time the Soviet Union orbited Sputnik as was NASA. Its charter is to pursue high risk but high payoff research projects which will keep the Nation at the technological forefront into the indefinite future. It counts among its accomplishments many of the most important technical advances made by this country in each decade since its creation. Its success has been in large measure due to the extremely high quality and dedicated technologists who have served on its staff and the autonomy and flexibility afforded by its special relationship with the White House, the Secretary of Defense, the Congress and the research community. I am proud to have been associated with DARPA as its Director over the past four years.

However, I must report to you and the rest of Congress that the problems I have outlined above for Defense Research are beginning to have a marked effect on DARPA's ability to continue its proud history of accomplishment. DARPA's vitality is maintained by turning over its technical staff every three to four years. Even though its scientific and engineering reputation remains high,

the "personal sacrifice" issue is clearly beginning to reduce DARPA's ability to attract "star quality" men and women to manage its research programs. Moreover, the regressive contracting rules and procedures now being applied to DARPA procurements are limiting its ability to maintain close and friendly relations with the scientific community. I suspect that the other mission agencies are suffering similar problems.

Both the Congress and the Executive branch should move quickly to resolve these problems so that DARPA may continue its great contributions to the Nations technical and national security interests.

DISCUSSION

Mr. FUQUA. Thank you very much, Bob.

How does the DOD determine what basic research is relevant to its mission?

Dr. COOPER. Again, that pretty much is done on a program and individual basis. As you know, the Defense Department's basic research programs and its early exploratory development programs are largely funded out of the scientific research offices.

The Office of Naval Research has been the largest of those fund sources. The policies that are set by the Director of Naval Research and by the staff and the research management in both the civilian and the military part of the Navy R&D structure determine what the important problems are for the Navy and where major investments are to be made.

But, by and large, the Director of Naval Research, in his job as head of the ONR, is able to pick out the particular topics of interest and to give direction to his staff as to where the important topics to be funded would be.

It is no different in DARPA. The Director of DARPA essentially sets the directions for the agency. The office directors, and the program managers follow that and seek and try to draw from the scientific community research proposals that will address the major issues that are defined.

In order to ensure that those directions are connected to the needs of the operational military commands, there are strong connections between the scientific infrastructure in the military departments and the operational elements of that at the senior management level—personal contact, by and large, but many formal contacts as well—at the middle management level where programs are actually worked on, and at the program manager level where research is really funded and monitored.

Almost all research of consequence in the Defense Department is done on contract outside, either in universities, in scientific laboratories in our industry, or in private companies of one sort or the other. A very small amount of the basic research activities now really resides in our defense laboratories. Those laboratories, by and large, are used to help monitor ongoing development activity and to provide scientific and technical bases for making decisions on procurements of various kinds.

The laboratories are, in my judgment, in sad shape for that reason, that it is even more difficult to draw high-quality technical people into those organizations which have down through the years been affected by the personnel policies and by the change in mission. There is not enough engineering and scientific research activity going on in the laboratories to really interest and draw in the high quality people. Consequently, I believe the quality of the advice that is going to our equipment procurers is not of the highest caliber from the defense laboratories.

Mr. FUQUA. You suggested in your statement that there be some policy for short-term appointment of scientists to DOD labs paid at a rate equivalent to their private sector salaries. Would you think that should apply more broadly than just to DOD, say, to NASA and some of the others?

Dr. COOPER. Yes, sir; I do. I believe that would be an excellent technique to try to reestablish the quality of our scientific and engineering expertise in Government, that is, to create what I am sure will be looked upon by the Office of Management and Budget a scientific elite within the Federal Establishment, short-term appointments with perhaps even a restriction that those appointments not be extended beyond the term for which they were initially provided.

Mr. FUQUA. Would not this add to the same problem you were talking about at DARPA where you have turnover, you have no residual company memory, as you referred to it I think, or institutional memory?

Dr. COOPER. I count that as a major plus. I believe that the lack of vitality——

Mr. FUQUA. That doesn't apply to Congress, now.

[Laughter.]

Dr. COOPER. I think the voters and the people who set up the Constitution provided for the tenure of our elected officials.

But I do believe that in research, particularly—it may not be true in legislation—but in research particularly, it is very important to get turnover, that is, to bring in new thoughts and ideas and minds into the process. That is why the institutionalization of laboratories per se, the national labs which have been studied to death over the last few years, the NASA laboratories—I was a manager, director, of a NASA laboratory, and I can see the problems. It is difficult to bring the young people in and to encourage the older people who probably should move on to other endeavors to move out. It is very difficult to do that.

We need to set up a process to do that. That is why DARPA has been so successful. It has no laboratories. There are no institutions that it supports. It has a policy of 4 years max. If somebody comes in and wants to stay beyond 4 years, there has to be a very good reason to do it. I think the vitality that that puts into an organization is essential in the research and development enterprise.

Mr. FUQUA. Before I call on Mr. Lujan, we are very honored this morning to have one of our fellow parliamentarians from Switzerland who also I think was the first woman to serve as a cabinet member in that government, the Honorable Lillian Uchtenhagen. Well, I guess she has stepped out for a moment.

Mr. Lujan?

Mr. LUJAN. Thank you, Mr. Chairman.

I only have one question. Looking over the testimony, you have given about 17 different recommendations of things that should be done. With the exception of personnel, this 3-year contract, and the contracting regulations, most of those 17 recommendations are in fact regulations rather than laws.

Dr. COOPER. That is true.

Mr. LUJAN. Is there any effort to move them within the Department rather than changing laws?

Dr. COOPER. Yes; there have been attempts over the past several years to, I would say, ameliorate the onset of many of these regulations. But you have to realize that many of the regulations and management practices that we have are responses and reactions both to the Congress and to public opinion.

What the Defense Department is doing to itself in the contracting area now with the creation of competition advocacies and very long processes of review upon review upon review of every single thing, seeking out waste, fraud, and abuse are all reactions to congressional criticism and public opinion which is being heaped upon the Defense Department at an enormous rate, probably mostly undeserved. So, the system reacts. It overreacts, so the tendency to inflict wounds upon ourselves in these processes is very great.

I think what we need is moderation in this process and a recognition, perhaps, that the defense research business is different from the procurement of aircraft carriers and toilet paper. It must be viewed differently and accomplished differently. The whole process of managing it should be different from the process of managing the MX project or something of that sort.

In other words, we don't take realistic attitudes. We tend not to have management experts in the Defense Establishment. The short-term political appointees—the quality of those hasn't been all that great in recent years. Their management experience is not great.

I had a great deal of difficulty when I was there finding anyone who knew anything about science and engineering in the Defense Department aside from myself. The problem is that we are not able to draw those people in at the senior level either, for obvious reasons.

How many people do you know who are in the prime of their scientific and engineering career who would be willing to take a factor of three cut in their salary, come into the Defense Department, and stay even for a couple of years and take all of the nonsense that goes with these terrible management practices that go on there? Well, there aren't many these days. There used to be many more.

Mr. LUJAN. But when you say a cut by a factor of three, you are talking about the heads of industry taking that kind of cut, not the average guy who is working for Hughes or one of the—do I dare mention more companies?

Dr. COOPER. Let me give you an example. The Under Secretary has been seeking a new Director of DARPA since I indicated to the Secretary that I would probably be leaving, and that was last November. He has been seeking one ever since, essentially, both—before Don Hicks came, the Secretary and the Deputy Secretary staff were looking for a new Director of DARPA. Since Don came, he has been seeking a new Director of DARPA.

A typical Director of DARPA is, I would say, a man in his mid-forties. He is at a mid- to high-level position in industry, perhaps head of a laboratory somewhere. His salary and fringe benefits may range from $120,000 to $210,000 a year. He comes into the Director of DARPA position and he has to settle for $70,000. Now, that is two to three times salary cut if he is at the high end of that. The Director of DARPA is a high level position in the Defense Department, but it is not an Under Secretary. It is not an Assistant Secretary of Defense. It is sort of middle level management position in a sense.

Mr. LUJAN. On the other side of that, you have people within the Department move up. You have many people in the national laboratories that don't—and I am not seeking an argument in this——

Let me ask you about the set-aside. You call it a 10-percent opportunity reserve. We have that in the national laboratories, perhaps not at the 10 percent level. I just assumed that we had it all over so if some opportunity comes up you can take a look at it and see where it comes out—but we don't?

Dr. COOPER. Typically, there are not adequate reserves in our basic research and exploratory development accounts to flexibly meet the opportunities that are there.

Mr. LUJAN. There are some, though.

Dr. COOPER. There are some, but by and large they tend to result from both planning changes that result from exigencies of one sort or another, plans that one made that just can't be accomplished and so the funds become available for some reason. They are not planned funds. Or from a conscious attempt on someone's part to try to set up such arrangements so that the contingency will be there.

The fact of setting aside a contingency account and making it known to the general management of the Defense Department, if one does that, it disappears. Or if one lets the Congress know that is happening, it disappears.

Mr. LUJAN. Ten percent would be $4 billion in the case of the Department of Defense.

Dr. COOPER. That is true.

Mr. LUJAN. You think that kind of money is needed?

Dr. COOPER. I think that there are $4 billion worth of opportunities in a $30 billion budget that occur every year.

Mr. LUJAN. Thank you, Mr. Chairman.

Mr. FUQUA. Mr. Brown?

Mr. BROWN. Dr. Cooper, I find your testimony extremely helpful and enlightening. I regret that the search is on to replace you. I doubt if it will produce anyone with your background.

Tell me, first of all, this administration has recognized the importance of more flexibility in personnel procedures as have most administrations, and it has been evidenced by such things as developing a more flexible supergrade work force. For example, in the upper levels, it is now possible—I forget what they call this elite group, but they can be transferred around.

Dr. COOPER. Senior Executive Service.

Mr. BROWN. Senior Executive group, and I presume that that reflects a desire to achieve some of the kinds of flexibility that you are talking about for the scientific community.

Dr. COOPER. Typically, I think the Senior Executive Service was set up to create a career individual who intended to come into Government, stay there, and to make Government service his life's work.

Mr. BROWN. All right. I see that distinction, but we have several categories here. We have the Exempt service, the political appointees who can be moved in and out at the discretion of the Executive. Then we have the career executive group that can be moved around but whose career presumably is protected. You are suggesting the need for an elite scientific group that basically would be

short-termers but who could move in and out of Government in pursuit of their scientific career and make their contribution.

Is there any reason in principle that this would not represent a continuation of this same philosophy of enhancing the effectiveness of Government as long as it could be suitably limited to prevent abuses? That is the reason we have these bureaucratic regulations, you know.

Dr. COOPER. I understand.

Mr. BROWN. It seems to me, philosophically, that what you are suggesting is quite compatible with the concept of a flexible, highly qualified group of people available to serve the Government with more or less flexible compensation procedures. Actually, the move which I understand is taking place now to decentralize personnel management from OPM back to the agencies moves in that direction and would give the Department of Defense, for example, as well as other departments, some at least more flexibility in developing systems that would meet that.

Is that your understanding?

Dr. COOPER. Yes, sir. That is my understanding, and I think that is a move in the right direction.

I should point out that such a flexible short-term scientific elite category was established in the 1960's by law. It was called a Public Law 313 appointment. When I first came into the Government in 1972 it was as a Public Law 313, and it took a total of 6 weeks for me to decide to do that, to move my family down to Washington, and to start working.

Currently, in order to move into an SES position, it may take 9 months to maybe 1 year and a half from the time you close with the person and he agrees to do it before you can get him into the Government. That is not flexibility.

Mr. BROWN. What is the reason for that? Is it due to the sheer bureaucratic growth of the Government?

Dr. COOPER. No, I believe there are some potentially good reasons for it. For instance, if the person comes into Government with the intent of making Government a career, it behooves the Government to make absolutely certain that this is the person they want and that he is well qualified and that he has all of the qualities needed for the job and for other potential jobs that he may have to hold in the future. So, the system moves with great caution.

Of course, all of that is centralized in OPM, so all of the approvals must go all the way through the Defense Department which has enough layers to make most layer cakes look trivial. Then, it has to move over across the river where there seems to be some kind of a time warp right at the Potomac. So, the whole process just takes a great deal of time.

There is no reason to do that in the case of short-term scientific appointments where the need is for highly qualified people to manage research programs for a short period of time with the understanding that they will leave after 3 or 4 years.

Mr. BROWN. You have indicated in response to a question from the chairman that the same need exists in other agencies which have a strong research and development responsibility. So, in a sense, if we were to consider the possibility of doing this for DOD, you would set up an invidious situation in which the other depart-

ments, say, Energy or NASA, would say, well, we have the same needs. Why can't we have a government-wide system subject to certain controls to maintain parity and equity that would operate for all the departments?

Of course, that is what this task force is looking at, Government-wide improvements in the management of science and research that would help us to achieve more effectively the goals that we are seeking.

Dr. COOPER. My experience with other organizations, NASA, Energy, National Science Foundation, is that they would also benefit from such flexibility.

Mr. BROWN. Yes, as long as it was carefully defined, I presume. You have pointed to the fact that even in NSF, a lot of the people that they use, and they use short-termers there——

Dr. COOPER. Yes.

Mr. BROWN. But they use them for what you described as paper shuffling, I think.

Dr. COOPER. Yes.

Mr. BROWN. And not for the kind of creative research management that you think the Department of Defense needs.

Dr. COOPER. That is right. And I think the National Science Foundation could benefit from higher quality short-term appointments. I believe that Eric Bloch has had a lot of success in bringing new people into the organization and increasing the quality of the management there. But I think that if you gave him the kind of flexibility that I am talking about that he could even do better.

Mr. BROWN. I would have to investigate this, but I think they have that particular category now where they bring in people from the universities for a 3- or 4-year term or whatever it is, and then they go back to the universities. I don't understand the specific rules and regulations, but if they can do it, surely the Defense Department could do it given the necessary flexibility in pay.

You want to attract, I think, people with a greater research management capability. They are looking for people who have the capability of handling peer review processes.

Dr. COOPER. Yes. I believe you are correct. There is a process in the Government called the Intergovernmental Personnel Act which does allow——

Mr. FUQUA. Rotators.

Mr. BROWN. Yes, they are called rotators.

Dr. COOPER. Yes, and it makes it easy to get people out of universities into Government for a short period of time under certain restrictions and constraints. The problem is that many of the scientists and engineers whom the Defense Department needs probably must come from the defense industry and are not eligible for this.

Mr. BROWN. And their pay scales are considerably higher. Of course, they don't have the side benefits that come from tenured university positions.

It seems to me—you have looked back at the golden age, I think, that you described in the sixties. The situation you are describing as desireable is one which we actually had much more. I recall the Office of Naval Research seemed to have had much more flexibility in dealing with management of their research projects, both in the

nature of the projects and the nature of the contracts that they executed.

Is that true?

Dr. COOPER. That is true. And the laws and regulations since the sixties which have been slowly accumulating and have caused the defense acquisition regulations to be a pile about that tall have really put a damper on that process. And the internal management practices have changed immutably toward less and less flexibility.

Mr. BROWN. Let me ask you this. You have come recently before entering this position from a position with SBS. Is that right?

Dr. COOPER. That is correct.

Mr. BROWN. Would you compare the nature of the arrangements that you had in SBS with what you find in Defense Department? Did they have some of the degrees of flexibility that you are recommending here in that organization?

Dr. COOPER. Absolutely. As a matter of fact, I would compare the situation at SBS with the situation at DARPA 10 years ago. DARPA has a great deal of flexibility compared to any other defense research organization or any other research organization in Government. It is a unique capability. Its board of directors, essentially, is the Under Secretary, the Secretary of Defense, and the Dep Sec Def, three people. The great power and authority that is vested in the Director of DARPA makes it possible for him to move quickly.

At SBS, we had three partners, Comsat Corp., IBM, and Aetna Life & Casualty. Each one of those had a board member. So, there were three guys. They came every month or couple of months, every quarter, to view what the company was doing. The president had great power and authority to do what he thought was right in that business within his business plan. The vice president for engineering had complete authority to do anything, change anything, in the system that was being developed there in order to meet the goals and objectives of the business plan.

Almost exactly the same situation that DARPA is in or was in 10 years ago. Contracting ability—I could make any contracts I wanted to on the outside. They had to be within the laws of the United States, but I had a great deal of flexibility. I could deal directly with the people with whom I was contracting. I could take them to lunch and we could discuss business over lunch.

Mr. BROWN. Three martinis?

Dr. COOPER. Martinis or no, business could be done in that way, very close relationships, and it worked well and we developed an entire communication satellite system in about 3½ years, built three of the first satellites, put two of them in orbit, set up the first three customers with ground stations, built a satellite control facility, and controlled those satellites all in about 3½ years.

Now, the capability there is about comparable to what the Defense Department wants to buy in Milstar. It is about the same complexity of a problem. I would suspect it will take 15 years for the Defense Department to built a Milstar system and get it up there and get it operating and get some of its first customers under service.

The question is, why is that? It is because no one is in charge of that process and everyone is. That is a serious problem for the De-

fense Department. We find ourselves unable to concentrate the power and authority to move in individuals and hold them responsible for making it happen and then giving them the resources they need to do it and checking them from time to time, not every day or every hour and every minute and not with the entire Federal bureaucracy, but with people who should have that responsibility.

If we could just find ways to do that, we could buy systems at 30 cents on the dollar to what we are paying now, and we would get them in 3 to 4 years rather than in 13 to 14 years.

Mr. BROWN. Well, that is impressive testimony, Dr. Cooper. I hope we can make some improvements along that line.

At the risk of throwing a damper on it, I don't think that flexibility made SBS profitable, did it?

Dr. COOPER. Well, the concept of a satellite business system was in itself a flawed concept. The system itself is a marvelous system. The concept of the business that it was to address was a flawed concept, but I think the system now is being used in a different business in ways that are highly profitable.

Mr. BROWN. I really didn't mean that to be an indictment, because we have one of the most effective research systems in the world in our agricultural sector, and it still hasn't made agriculture profitable either, so I don't know what the answer to that particular question is.

Dr. COOPER. I think the business plan is flawed. [Laughter.]

Mr. BROWN. There is something else necessary here.

Mr. Chairman, I won't prolong this, although I have a number of other questions.

Mr. FUQUA. We have two other witnesses.

Mr. BROWN. I know you do.

Mr. FUQUA. We will have to move along.

Mr. Lewis, do you have questions?

Mr. LEWIS. No, thank you, Mr. Chairman.

Mr. FUQUA. Thank you very much, Dr. Cooper, for being here.

Dr. COOPER. Thank you.

PANEL: SCIENCE IN THE DEPARTMENT OF DEFENSE

Mr. FUQUA. In the interest of time, we are going to take our next two witnesses together and then have questions afterwards. Our next witness will be Norm Augustine, executive vice president of Martin Marietta and former chairman and current member of the Defense Science Board. He is also the author of a very interesting book called *Augustine's Laws* and owner of a copyright on a slide rule for baseball managers. Maybe Dick Howser used that last night.

Following Norm Augustine will be Mr. Rodney Nichols, chairman of the American Association for the Advancement of Science Committee on Science, Arms Control and National Security. In addition, in his spare time, he is executive vice president of Rockefeller University.

Mr. Augustine, we would be pleased to hear from you and then from Mr. Nichols.

[A biographical sketch of Mr. Augustine follows:]

NORMAN R. AUGUSTINE

Norman R. Augustine was born July 27, 1935 in Colorado and attended Princeton University where he majored in Aeronautical Engineering and was awarded a BSE, magna cum laude, a MSE, and was elected to Phi Beta Kappa, Tau Beta Pi and Sigma Xi. After graduation he took courses at Columbia University Graduate School of Business and UCLA.

In 1958, he joined what is now the McDonell Douglas Corporation, holding titles of Research Aerodynamicist, Chief Engineer and Program Manager. In 1965 he joined the Federal Government in the Office of the Secretary of Defense, occupying positions including that currently designated as an Assistant Undersecretary of Defense for Research and Engineering. Upon joining the LTV Aerospace Corporation in 1970, he served as Vice President, Advanced Programs and Marketing, for the Vought Missiles and Space Company. Mr. Augustine was nominated by the President and confirmed by the Senate in 1973 as Assistant Secretary of the Army (Research and Development) and in 1975 as Undersecretary of the Army. In 1977, he joined Martin Marietta Corporation where he has served as president of the 20,000 employee Denver Aerospace, senior vice president of the Information Systems group, and is currently executive vice president of the corporation.

He is chairman of the NASA Space Systems and Technology Advisory Committee and has served as president of the 35,000 member American Institute of Aeronautics and Astronautics, president of the 160,000 member Association of the United States Army, chairman of the Aeronautics Panel of the Air Force Scientific Advisory Board, and chairman of the Department of Defense's senior advisory group, the Defense Science Board. He has been elected to the National Academy of Engineering and the International Academy of Astronautics and is a Fellow of the American Astronautical Society, an Honorary Fellow of the American Institute of Aeronautics and Astronautics and a member of the Institute of Electrical and Electronic Engineers. He is a licensed professional engineer in the state of Texas.

Mr. Augustine has served on Boards of Directors of the Colorado National Bank, International Laser Systems, Inc., the American Helicopter Society and the Air Force Academy Foundation, and is a Member of the Corporation of the C.S. Draper Laboratory and the Board of Governors of the Research Triangle Institute. He has been on advisory boards to the Executive Office of the President, the Departments of the Army, Navy, and Air Force, the Department of Defense, the Department of Energy, the Department of Transportation, NASA, the General Accounting Office, the National Academy of Science, and NATO. He is a member of the Board of Regents of the Institute of Cost Analysis, a member of the Board of Advisors of the Society of Logistics Engineers, and a trustee of the Vertical Flight Foundation. He has chaired advisory councils for Princeton University, The American University and the MIT Lincoln Laboratory; has served on advisory boards and boards of visitors ot the University of Colorado, Georgia Tech, Duke, Texas A&M, Florida State, and the Defense Systems Management College and is an Honorary Member of the Faculty of the Industrial College of the Armed Forces. He has been an Associate Editor of the *Defense Systems Management Review* and served on the Editorial Boards of *Astronautics and Aeronautics* magazine and the *Journal of Defense Research*.

He has been awarded the Department of Defense's highest civilian decoration, the Distinguished Service Medal (three awards); the Defense Meritorious Service Medal; the Army Distinguished Service Medal; and the Air Force Exceptional Service Medal. He is a recipient of the American Astronautical Society's Military Astronautics Trophy, the American Defense Preparedness Association's Gold Medal and Knowles Awards, the National Contract Management Association's Roback Award, and is an Honorary Command Sergeant Major of the U.S. Army.

Mr. Augustine has chaired a national committee of the Boy Scouts of America, held adult leadership positions with the YMCA, served on the Board of Directors of Colorado's minority education INROADS, and is a member of the Western Stock Show Association. He is married to the former Margareta Engman of Stockholm, Sweden, and they are the parents of a son, Gregory, and a daughter, René. He is author of the book entitled *Augustine's Laws*, holds a copyright on a slide rule for baseball managers, and is listed in *Who's Who in America*.

STATEMENT OF NORMAN R. AUGUSTINE, SENIOR VICE PRESIDENT, MARTIN MARIETTA CORP., BETHESDA, MD; AND FORMER CHAIRMAN, DEFENSE SCIENCE BOARD, U.S. DEPARTMENT OF DEFENSE

Mr. AUGUSTINE. Thank you, Mr. Chairman and members of the committee. It is a privilege to have this opportunity to appear before you this morning.

With your permission, to save time for questions, I propose I submit my formal statement for the record and summarize extracts of it in about 10 minutes. Would that be acceptable?

Mr. FUQUA. Yes, sir, as long as you assure me it will be shorter than the prepared statement.

Mr. AUGUSTINE. All right.

There are, I believe, four characteristics that help describe science and technology today. They would be that they are big, the pace of change is fast, they are increasingly international in nature, and they are characterized by unpredictability.

One often hears the term big science today, and in the scale of impact, science is indeed big by almost any standard one might have. It has been estimated that over half the scientists who have ever lived are alive as we meet here this morning.

Increasingly, scientific progress has been dependent upon large teams of scientists and engineers working together in complex and costly laboratories. I believe the cost of those laboratories is one of the major reasons why the Government has a significant role to play in supporting science.

I should at this point also say that I am not a scientist personally. I am an engineer, so my comments come from that perspective.

Regarding the pace of change of science and probably more measurably the technology, it has been indicated that the half-life of change of technology ranges on the order from 3 to 10 years for the hard sciences. In the fields of electronics, communications, information systems, and the like, the half-life is probably 2 to 3 years. The pace is suggested, for example, by the fact that the number of lines of code of software extant in the United States today doubles about every 14 months.

Clearly, scientific and technological activity is also becoming much more international in character in recent years. As other countries grow stronger, both economically and in terms of their academic systems, it will be very difficult for the United States to enjoy the kind of a lead it has had in all fields of technology continuing into the future. At the same time, I believe with a degree of selectivity, we can maintain a significant lead in those truly pivotal areas of technology.

I might at this time, picking up on a point of Dr. Cooper's, say that the finest work in the laboratory by scientists usually evidences itself in a form of lead time over the time in which other scientists in other laboratories gain that same information. It is very easy to squander that hard-earned lead in the implementation process, either through mismanagement, bureaucracy, or what have you. I think that is a very important thing for us to keep in mind.

I would also point out that, in my view, science is probably best pursued in an environment of relatively free inquiry unencumbered by rigid schedules and scope constraints. That is not to suggest that science has to be conducted as a large Montessori playground or that it has to be totally chaotic. On the other hand, I think we do have to give our scientists the freedom to explore peripheral opportunities that arise and to exploit the targets of opportunity that they learn of.

I would like to turn now to the impact that various institutions in the sense of mission agencies in the broadest sense might have on the science and technology generation process in the United States. I would like to begin with the largest player in that scene, namely, the Federal Government.

The Federal Government is, in my opinion, and should continue to be a very major factor in the area of scientific research, particularly as a provider of funds for selected applications. I will elaborate on that in a moment.

On the other hand, it is my own belief that the Government should be principally a policy setter and overseer to provide leadership and oversight rather than merely another competitor, although a very large one, to the research capabilities in universities, industry, and other types of institutions. I have found that it is particularly hazardous when the Government seeks to act as both judge and jury in the area of scientific research to decide which projects should be funded when the Government itself is to be a player in carrying out some of those projects.

Turning to the role of the industry, it is with a considerable degree of disappointment that I have to advise the committee it is my belief that industry in the United States cannot, by and large, be counted upon for a major role in performing truly basic research. By that I mean long-term, relatively undirected, relatively high-risk, and often costly research.

The market forces in the United States today disappointingly are such that performance is expected in a period of years, perhaps even quarters. Whereas in Japan they speak of a 25-year plan, a 5-year plan in this country is very difficult to follow, and research just doesn't function on that type of a span.

Happily, there are exceptions to what I have just said, but I think they are that. They are just exceptions.

I would like to mention also the role of the independent research and development program which is so important to industry and permits us to do two things. One, write proposals for new business and, second, to perform research and advance the state of the art. The type of pressures that Dr. Cooper has described are causing us to devote an increasing portion of that money not to the conduct of research but rather to the writing of proposals and the filling out of forms and the paperwork. I think that probably has hurt all of us. That trend is probably hurting all of us.

Turning to academia, my own view would be that our universities probably are a key to the future of scientific research in the United States. At the same time, I would have to say that unlike many of my colleagues with whom I speak, it is my belief that the principal role of the university is to educate rather than to perform research. I happen to believe that many of our universities have

caused that balance to swing too far in the direction of research at the expense of education. I would hasten to emphasize, though, that I believe both are important for a fine university, but I think a degree of balance is required.

I would like to turn to several specific issues that have been raised by this committee. One is the matter of advisory boards. I believe that an enormous amount of expertise has been made available to the Federal Government in the form of advisory committees. I see many of these committees with groups of people that frankly would have been impossible to gather in any other form I can think of simply because the talent level is such and the pressure on their time is such that they are just not available in a single group either to be called upon by an industrial firm or any other element that I can think of.

At the same time, it is becoming increasingly difficult to form advisory committees of that type because of the conflict of interest concerns. I should say that those conflicts can apply to individuals from academia as well as those of us from industry, and that people in academia, particularly in the hard sciences, generally are involved in consulting arrangements and they also have investment portfolios which relate to their field of expertise.

Currently, one must have integrity in the advice being given to the Government. We must have advice without reproach. Unfortunately, I don't have a solution to this concern I raise. On the one hand, I am convinced that one can't legislate integrity. On the other hand, I am convinced that one can't afford to have advisers not motivated by the highest principles.

For whatever it might be worth, I could note to the committee that it has been rare, indeed, that I have ever seen cases where I felt an adviser was acting in other than the best interests of the advised. The reason for that is simple. That is that one's stature as an individual scientist or engineer could not long endure any other type of behavior in the eyes of one's peers.

I would like to briefly give five recommendations to the committee. First is that it is of the utmost importance that scientific research be adequately funded. A major part of the viability of our industrial sector will depend upon that.

Second, we must provide stability. That is difficult to do in changing times with a changing technology, but scientific research is very difficult to turn on and off.

Third, as I mentioned, we must provide our science a good deal of latitude to perform research and pursue opportunities that may arise. We must not overly constrain them with contractual requirements.

Fourth, as with any endeavor I guess, the key to success tends to be the people who are involved. Our Federal Government must have the highest quality people if the Federal Government is to deal with the enormous sums of money that it has to allocate and the major decisions it must make.

Today, it is becoming increasingly difficult to hire that caliber of people in the Federal Government. I see it from the other side from what Dr. Cooper described where I see how easy it is for those of us in industry to compete for talented people with the Federal Government. I think that is a very unfortunate trend for the Nation,

and I would be happy to address that should the committee like to raise any questions.

Finally, I would like to mention the need for organizational latitude in permitting the universities, the research institutes, the industry, and the Government in this country to work together. At the present time, we have somehow managed to create an adversarial situation between many of those that I have just mentioned. We are finding that we can't compete, for example, against Japan where they have successfully brought such groups together.

The antitrust concerns are very real and very appropriate. But there is a degree to which one can carry that which is counterproductive to our ability to compete in the international marketplace. I think we have seen that in our attempts to compete, particularly, with the Japanese who have been so very effective.

I believe that is a good place to stop with a summary of my statement, Mr. Chairman and members of the committee. Again, I thank you for your interest in what I believe to be a very important field, and I appreciate the chance to share my views with you this morning.

[The prepared statement of Mr. Augustine follows:]

STATEMENT OF

NORMAN R. AUGUSTINE

***

COMMITTEE ON SCIENCE AND TECHNOLOGY

U. S. HOUSE OF REPRESENTATIVES

***

Washington, D. C.

23 October 1985

Mr. Chairman and members of the Task Force, it is a privilege to have this opportunity to share with you my views on Science Policy and, in particular, the manner in which the mission agencies and federal laboratories relate to that policy.

I feel relatively certain that every witness who has ever appeared before a Congressional hearing has expressed the view that the subject at hand was of transcending importance. Truly, however, this would seem to be the case with regard to the matter of establishing a national Science Policy, for reasons which I will relate shortly. I would, therefore, like briefly to discuss some current trends in science and technology in the United States and to address the role of the various institutional participants in the conduct of science and technology activity. I would then like to close with several recommendations for the betterment of this effort.

It is perhaps appropriate to begin with a few caveats which may be helpful to the Committee in assessing my testimony. First, I myself am not a scientist; I am an engineer. Simply stated, I am not personally active in (although certainly greatly impacted by) the effort to roll back the frontiers of knowledge. Rather, whatever contribution I may have made lies principally in the realm of applying new scientific knowledge, hopefully to the betterment of mankind. Second, the views I will express are solely my own and do not necessarily reflect positions of the various organizations with which I have had the privilege of being associated over the years. Third, my perspective is not the crisp, experienced viewpoint of one who has spent an entire career in a given type of mission agency. Rather, my "biases" reflect a combination of experience I have gained working in large industrial firms, in a university research laboratory, on advisory boards to a number of universities and not-for-profit organizations, serving on the board of directors of small entrepreneurial firms, and of course, in my service in government as well as in an advisory capacity to the government. With that caution that my background is one of breadth rather than depth, I would like to proceed to share with you my views on the subject of a national Science Policy.

First, I know of no pursuit having greater leverage, in terms of its impact on society, other than education itself, than scientific research. A number of the most pressing problems facing the United States and the world today have as at least an element of their solution, scientific and technological advancement. These problems cover a spectrum which includes the creation of jobs to stimulate the economy and restore the trade balance, the continued provision of energy as existing sources dwindle, assuring the peace through strong national defense, providing for the health of our citizenry, and helping assure adequate food supplies for the world.

Four characteristics which help to describe science and technology today are that they are big, their pace of change is fast, they are increasingly international in nature, and finally they are characterized by unpredictability.

One often hears the term "Big Science." Science today, in the sense of both scale and impact, is indeed "big" by almost any definition of the word. It has been estimated that over half of the scientists who have ever lived are alive at the present time. Increasingly, scientific progress is dependent upon large teams of scientists and engineers working together in complex and, unfortunately, costly laboratories. The growing price of facilities is one of the most fundamental factors in making government financial support of science a necessity.

The pace of change of science and, more measurably, technology is indicated in the fact that by almost any measure the half-life of technology is today on the order of three to ten years, depending upon the particular discipline under scrutiny. In the burgeoning area of information technology, for example, which represents the confluence of the fields of computers and communications, the doubling times of capabilities (such as the number of circuit elements on a chip) are measured in terms of a mere two to three years. The magnitude of the information technology explosion is also evidenced by the fact that the number of software lines of code extant in the United States is doubling every fourteen months. Yet, few of the fundamental ingredients which have made all this possible were even contained in the existing body of knowledge a mere three decades ago.

Clearly, scientific and technological activity is also becoming much more international in nature. As other countries build stronger economies and educational systems, it seems inevitable that the U. S. will become less dominant in the overall sense. This does not, however, mean that we cannot or should not maintain important leads in selected, critical areas of science and technology. Further, it is important to note that scientific leadership can be measured in terms of "time" -- usually a matter of a mere few years -- and that in terms of impact, that hard-earned lead can easily be squandered in the process of moving from the laboratory into practice.

Finally, the unpredictability of the effort to advance science and technology is widely recognized. Albeit very frustrating to managers, the impact of this uncertainty is of the utmost importance in creating a national science policy. This property of science has lead, one might note, to the embarrassment of even some of the more capable scientists in the world, not to exclude such giants as Lord Kelvin who assured us that "x-rays are a hoax," or Thomas Edison who is said to have noted that "fooling around with alternating currents is just a waste of time." When seeking to establish a definitive and explicit science policy, it is humbling to realize that penicillin was discovered only when Sir Alexander Fleming happened to observe that bacteria did not grow in a portion of a culture that had been accidentally contaminated by mold, or that synthetic fibers were the result of a researcher's observation while watching a

reaction vessel used in unrelated polymer research. Or that a catalyst critical to the formulation of artificial rubber was found only when a mercury thermometer, being unjudiciously used as a stirring rod, accidentally broke. Or that the search for artificial sweeteners was unexpectedly propelled forward when a researcher working in another field noticed a sweet taste to a cigarette that had been resting on a laboratory bench. Or that William Roentgen discovered x-rays while investigating not x-rays but cathode rays. Examples of this characteristic of science and technology are legion.

The lesson would seem to be that science is best pursued in an environment of relatively free inquiry, unencumbered by rigid schedules and scope constraints. That is not, of course, to suggest that research must be totally chaotic or that all areas of pursuit are equally likely to impact society in an important and favorable manner. It does, however, seem to suggest that research is best performed when given fairly broad latitude in terms of day-to-day conduct, within the bounds of overall areas of focus.

Turning now to the impact which various "institutions" can have on science and technology, perhaps one should begin with the federal government itself. The federal government is, and, in my view, should continue to be, a major provider of funds for scientific research. On the other hand, I believe the government should not itself, in general, be a major conductor of that research. This belief simply stems from my view that in a free enterprise system, government best serves the people when it functions as a provider of very selected resources, leadership and oversight, rather than as merely one more competitor, albeit a large one, in the world of day-to-day operations. My experience has been that particularly in the area of science and technology it is hazardous when the government, even inadvertently, finds itself in a role of being both judge and jury. This can and does occur when, for example, the government must determine whether or not specific projects are to be supported, yet some of the candidate undertakings would be performed by the government itself whereas others would be pursued by outside institutions. A logical question might be why the government should then be called upon to underwrite science and technology at all if the beneficiaries are principally within the free enterprise segment of our economic system. The reasons have to do with the scale, risk, lead time, and the breadth of impact of scientific research.

There are a number of more specific trends within the general area of federal support of science and technology which are potentially significant in the formulation of a science policy. As but one example, in decades past the efforts of the (Defense) Advanced Research Projects Agency were focused upon advancing basic research and applied research. Over the years since its inception, however, the funds allocated to DARPA have been, to an increasing

degree, used for prototype demonstrations -- a very worthwhile undertaking in its own right but nevertheless still a major drain on the basic research resources originally intended at the time ARPA was established. Similarly, in the early aviation program, the NACA was a major factor in building the research base used by the aerospace industry. Today, in the space program, probably of necessity because of the characteristics of that program, this role has reversed and the NASA has become the customer. Hopefully, as the space program matures, we will be able to realize the benefits of NASA's on-going effort to shift much of the "hands-on" part of the space program to non-governmental institutions.

Turning to the role of industry, it is with some regret that I must report my view that, by and large, industry in the U. S. cannot afford to undertake major, fundamental research efforts except in very selected instances. Our market-oriented society, unlike that peculiar to Japan and certain other nations, simply does not permit industry the luxury of pursuing large, long-term, high risk investments. There have, of course, been examples in the past of excellence in research in U. S. industry. The work of the Bell Telephone Laboratory stands out as a shining example, but even that organization, in essence, was a part of a regulated entity as opposed to a true free enterprise institution. I am simply not optimistic that industry itself can be counted upon to fund, on a significant scale, truly basic research. On the other hand, both large established firms and small venture capital firms are certainly effective at applying technology, and it is in this important area that we must be sure to create an environment which can nurture these bodies.

The role of the independent research and development program sponsored by the government to provide discretionary funds for its contractors to pursue research and technological activities is a significant factor in this regard. Unfortunately, its impact is now being diluted through the costs of increased reporting and oversight and, even more importantly, the requirement to devote large portions of the available resources to extensive proposal writing as opposed to the conduct of true research and exploratory development itself.

Turning to academia, my view would be that our universities are a key to the future of scientific research in the United States. At the same time, unlike many of my colleagues, I happen to believe that the primary role of a university is to teach. This is not at all to say that university research is unimportant, only that an appropriate balance of research and teaching needs to be maintained; and in my judgment, in many instances this balance has shifted too far away from teaching.

The establishment of research institutions associated in one of a variety of fashions with universities would seem to me to represent an excellent approach for achieving the balance that I believe is so necessary to both education and to the creation of knowledge. An additional important issue in this regard continues to persist with respect to the role of universities in research pertaining to national defense. Clearly, many of our nation's finest academic institutions have struggled with the propriety of pursuing research relating to military matters, particularly when that research is classified. At the same time, it seems clear that it cannot be in the best interest of the nation to invest major national resources in establishing defense-oriented research programs in universities only to find that these programs are terminated when the universities subsequently readdress their policies in response to concern over specific military events. Long-term positions need to be articulated so that the interests of both the universities and the government may be protected.

I would now like to turn to several specific issues that have been raised by this Committee as a result of its earlier deliberations.

Beginning with the matter of advisory boards, it is my overall belief that an enormous amount of expertise and experience is made available to the government through the forum of advisory boards and is done so at a very, very low cost. I have observed committee after committee made up of groups of individuals of a talent level that simply could not have been assembled in any other form than as an advisory board -- if for no other reason than the competing demands for those individual's time and attention.

However, in order for an advisory board to be effective, it must not only have competent members willing to truly "engage," but it must also have a sponsor who is truly interested in receiving advice. If one or both of these ingredients is not present, the success, or lack thereof, of an advisory board is predetermined. Several important issues still exist with respect to the government's use of advisory boards, the most important of which I believe to be those relating to the matter of possible conflicts of interest. Such potential conflicts, incidentally, can apply to individuals from academia as well as those from industry in that people in academia, particularly in the hard sciences, often have consulting arrangements and investment portfolios which relate to their field of expertise. My experience has been that it is becoming almost untenable to assemble a group which is competent and experienced in a given area, yet which has no connections in that same area which could lead even to a perceived conflict of interest. On the other hand, the integrity of the advice being given to the government must be absolutely without reproach. Unfortunately, I do not have a solution to this problem. I am, on the one hand, convinced that one cannot legislate integrity. I am equally convinced that one cannot afford to have advisors motivated

by other than the highest principals. For whatever it may be worth, I might note that it has been rare, rare indeed, that I have ever seen an advisor acting with what I thought was other than the best interests of the advised. One's stature as an individual scientist or engineer simply could not long endure such behavior. Nonetheless, a much clearer delineation of whatever is to be the government's policy in this regard is badly needed out of fairness to both the advisor and the advised.

A similar conflict arises in terms of the degree to which advisory committee meetings should be held in the public spotlight. Clearly, the public has a right and a need to know what type of advice its government is receiving. On the other hand, the existence of large and sometimes politically inspired audiences can be a severe impediment to the type of candor which is needed if advice is to be very useful. A mechanism affording careful balance in this regard is essential.

Finally, it has been my experience that most advisory committees tend to be reactive -- mainly reviewing inbeing activities rather than taking the lead in suggesting new and promising avenues to be pursued. This is perhaps the major failing of the advisory board process as it exists today.

Turning to the important area of research on behalf of the Department of Defense, important, if for no other reasons than its size and consequence, it is my belief that such research should be performed for the one and only purpose that it contributes to providing for the nation's military security. The argument that such research has peripheral social benefit or that it stimulates the economy, while fortuitous, does not seem relevant in terms of determining fundamental worthiness of support. That is, defense research should be supported to whatever degree is commensurate with the risk one wishes to accept in the area of national security; and beyond that, funds should be diverted directly to other purposes for the explicit pursuit of other benefits.

Research relating to national defense, as well as that associated with commercial endeavors, also poses certain particular problems in the area of dissemination of information. Research thrives in an open environment, with various researchers able to communicate rapidly and freely among one another. At the same time, in some instances, such communications can be harmful to the interests of our nation or even to those of an industrial firm sponsoring the research in question. I reluctantly conclude that industrial firms often must necessarily protect the findings of their research to a very high degree. On the other hand, in the case of basic research underwritten by the government, the nation as a whole may be best served by internationally pooling the information thereby derived, at least if that information is not explicitly vital to national defense. In most, but not all, cases the nation's commercial and military objectives can be accomplished

by erecting barriers to the dissemination of selected information relating to the application of scientific knowledge -- such as manufacturing techniques -- as opposed to seeking to restrain the flow of scientific knowledge itself.

Finally, the Committee has inquired as to what particularly promising areas of scientific exploration exist today. Certainly, the answer to this question deserves a great deal more discussion than is possible here, but in my judgment would certainly have to include bioengineering, nuclear physics, artificial intelligence (both robotics and knowledge-based systems), energy generation, micro-electronics, optics, and materials.

In the way of summary, I would like to offer five recommendations in the form of observations for the Committee's consideration.

First, it is of the utmost importance to the nation's well-being that fundamental scientific research be adequately funded and that a substantial segment of the needed support be provided by the federal government. Grants are a particularly effective form of such support, overseen by the well-established peer review process.

Second, stability must be provided in the research environment. This can perhaps best be accomplished through multi-year grants. Crash programs, such as the Manhattan and Apollo projects, can produce enormously successful and important outcomes, although their price often includes major disruption in human and institutional terms when those projects reach their conclusion.

Third, a great deal of freedom must be afforded scientists performing research to pursue their own approach and follow schedules dictated by the nature of the work itself. In addition, they need to have a degree of latitude to explore promising findings within the bounds of an overall area of concentration. I can assure the Committee from personal experience that it is very, very difficult for a manager to accept such a freewheeling concept. Most of us as managers are much more comfortable with specific objectives, specific schedules, specific budgets, and measurable milestones. Unfortunately, the attempt by the government to impose such a management philosophy on the conduct of research in order to avoid the possibility of occasional failures is, to an increasing extent, having the effect of reducing the possibility of occasional successes.

Fourth, as with most endeavors, the key to quality scientific research is the involvement of competent and motivated people. Our nation has been unnecessarily forgoing the potential contributions of a large number of talented individuals in this regard, as measured by the absence of females in a proportionate sense in the

technological workforce as well as by the difficulty the economically disadvantaged have in obtaining the necessary education to pursue scientific fields. In my judgment, the principal problems in the area of scientific education lie in our nation's high schools and secondary schools, rather than in its universities. It is also my belief that our universities best enhance our nation's scientific strength when they emphasize basic principals rather than areas of current, and often transient, public appeal.

It would not be proper to leave this subject of scientific and technical education without at least mentioning the large, controversial and multi-faceted role that foreign students and faculty play in our nation's graduate schools today, particularly in the area of the hard sciences. This subject is too complex, having important pros as well as cons, to dismiss in a few simple sentences. Let me simply observe that it is a matter worthy of careful thought in formulating a science policy. In the same vein is the matter of remuneration of government employees working in the scientific arena. If we truly believe that people are the key to success of scientific and technological undertakings, it is then false economy indeed for the government to pay inferior salaries and at the same time hope to keep the caliber of personnel needed to make the multi-million dollar decisions faced within government almost daily.

Fifth, there is a need to provide greater organizational latitude to enable our universities, the federal government, and U. S. industry to work together in the pursuit of research and technological activity. The long-standing concern in this nation over anti-trust activities is a real and proper one. At the same time, overly restraining legitimate pursuits because of unfounded anti-trust concerns can be enormously harmful to the interests of the United States in the world marketplace. Japan's activity in this regard is a clear case in point.

In closing, I would like to thank the committee for this opportunity to express my views on these contentious but important topics. I might note that when I had the privilege of serving our country as the Assistant Secretary of the Army for Research and Development, I steadfastly held the position that the adequate support of basic research was the number one priority of the Army's material acquisition program; more important on the margin than even development or production activities. The failure to discover radar, nuclear fission, the transistor, stealth airplanes, or for that matter, the Salk vaccine, could have had a truly decisive impact on our well being. That this committee is willing to dedicate the time to listen to over one hundred fifty witnesses on the subject of science policy is a very encouraging sign indeed to those of us engaged in the field. This may be particularly important when one realizes that a very major portion of the members of the Soviet Politburo and Central Committee are personally trained in the fields of science and technology, yet such backgrounds are relatively uncommon among individuals serving in the U. S. Congress or in the senior ranks of the Administration. Your interest is very much appreciated.

This completes my prepared statement. I would be happy to answer your questions.

Mr. FUQUA. Thank you very much, Norm.
Mr. Nichols?

[A biographical sketch of Mr. Nichols follows:]

RODNEY W. NICHOLS

Rodney W. Nichols, executive vice president of The Rockefeller University, is a specialist in research and development who has served with industrial, governmental, and academic organizations. He is the principal deputy to President Joshua Lederberg in planning and managing activities at the University, a center for research and advanced study in the biomedical and related behavioral and physical sciences.

Mr. Nichols came to the University in 1970 as special assistant to Frederick Seitz, then president, was elected vice president in 1972, and was elected executive vice president in 1978 at the beginning of Dr. Lederberg's administration.

From 1966 to 1970, he served as special assistant for research and technology in the office of the Secretary of Defense, working with the director of defense research and engineering. His principal responsibilities were in coordinating programs and funding for basic and applied science, assessing the relationships among the R & D efforts of various federal agencies, and analyzing issues raised by new Department of Defense systems and policies. Mr. Nichols frequently represented the Department in testimony before Congressional committees. He was awarded the Secretary of Defense Medal for distinguished and meritorious civilian service in 1970.

From 1959 to 1966, he held the post of manager of the Systems Analysis Laboratory of the research division of Melpar, Inc., a Westinghouse subsidiary. Initially working in experimental solid state physics, he was later responsible for the technical direction of an applied research group carrying out laboratory and computer-assisted studies for a variety of federal and other sponsors.

An analyst of the U.S. policies for science and technology, he has participated as a consultant with a number of organizations including: Office of Science and Technology Policy in the Executive Office of the President, Defense Department, State Department, Peace Corps, National Science Foundation, National Institutes of Health, Rand Corporation, General Telephone and Electronics Corporation's Research Laboratories, Georgetown University Center for Strategic and International Studies, Congressional Commission on Governmental Procurement, Library of Congress, Commission on the Operation of the United States Senate, the early 1970's physics survey of the National Academy of Sciences, and Congressional Office of Technology Assessment (OTA).

He has served on the Committee on Science, Engineering and Public Policy of the American Association for the Advancement of Science (AAAS), and presently is chairman of the OTA's Advisory Panel on long-range plans for advanced materials and their applications in manufacturing. He is a member of the High Technology Advisory Council of New York State's Urban Development Corporation.

In the international area Mr. Nichols has been involved in many studies concerned with the application of modern technology for civilian and military purposes. He was a member of the U.S. delegation to a special meeting convened by the United Nations on preparations for negotiations of chemical and biological arms control (Geneva and New York, 1969). Deputy chairman of the U.S. delegation to the U.N. Committee on Science and Technology for Development (New York and Geneva, 1973–78), he then was appointed to the U.S. delegation at the world-wide conference on technology for developing countries (Vienna, 1979). He was named by the U.N. Secretary-General in 1977 to the Advisory Committee for Science and Technology, the senior technical group advising the Economic and Social Council.

He was chairman of the Congressional Office of Technology advisory panel on strategic responses to an extended oil disruption. A member of the advisory committee to the State Department's Bureau on Oceans, Environment, and International Scientific Affairs, he is also chairman of the AAAS Board's Committee on Science, Arms Control, and National Security.

He has served on the Board on Science and Technology for International Development, and on the Board on Committee on Advanced Study in China, for the National Academy of Sciences. He has worked and travelled in Europe, Latin America, the Middle East, the Caribbean, and the People's Republic of China.

He is the coauthor of two books: *Research and Development and the Prospects for International Security* (with Frederick Seitz), published by Crane, Russak, & Co. in 1973, and *U.S. Military R & D Management*, published by Georgetown University in 1973. He also was chairman of a committee supervising the development of the *Verification Challenge: Problems and Promise of Strategic Nuclear Arms Control Verifi-*

cation, R.A. Scribner, T.J. Ralston, W.D. Metz, published under the auspices of AAAS by Birkhauser Boston in 1985.

Mr. Nichols co-chaired and contributed the lead paper to a panel of experts who met in Peru in 1983 and developed a volume entitled *Research and Development Linkages to Production in Developing Countries,* (editor M.P.W. Silveira, published under the auspices of the United Nations by Westview in 1985.

Mr. Nichols has lectured widely before professional groups and at universities including Yale, Columbia, Pennsylvania, Duke, and New York. He has written numerous articles and reviews for such journals as *Science, Minerva, Innovation, American Scientist, Physics Today,* and *Technology in Society,* of which he is a founding member of the editorial board.

Selected as a National Sigma Xi Lecturer for 1974–75, Mr. Nichols examined national trends in research and development. During the summer of 1975 and 1978, he was a featured speaker in two national CBS television series. The lectures covered the impacts and responsibilities of science and technology, and the post-World War II foreign policy developments affecting the scientific community.

Born in Evanston, Illinois on September 15, 1937, Mr. Nichols received an A.B. degree in applied physics from Harvard University and has had graduate training in the physical, biological, and social sciences. He is a member of the American Physical Society, the Council on Foreign Relations, and a Fellow of the American Association for the Advancement of Science. He is also a member of The Cosmos Club in Washington and The Century Association and 7th Regiment Tennis Club in New York.

Mr. Nichols is married to the former Carolyn McKnight, who was born in Louisiana and is a published novelist, senior editor and publishing executive at Bantam Books. They live in New York City with their son, Christopher, who was born in 1976.

STATEMENT OF RODNEY W. NICHOLS, CHAIRMAN, AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE [AAAS], COMMITTEE ON SCIENCE, ARMS CONTROL AND NATIONAL SECURITY; AND EXECUTIVE VICE PRESIDENT, ROCKEFELLER UNIVERSITY, NEW YORK, NY

Mr. NICHOLS. Thank you, Mr. Chairman.

In addition to joining my old friend, Norm Augustine, in congratulating the committee, I think that the morning shouldn't go by without somebody mentioning this superb review developed by the committee and staff on science policy issues. That has already become an interesting talking paper around the country in circles you may not have been aware of.

I submitted a prepared statement, Mr. Chairman, and would like to just zip through the statement highlighting a few themes and paraphrasing some of them. I would like to begin on a note that combines both some concepts and a little bit of funding data.

You posed the question of what will be the long-range implications of the reemergence of the Department of Defense as a major sponsor of basic and applied research. I gather that is at least one of the major issues under review this morning.

You have already gotten a good deal of data earlier this month about it, but in my prepared statement I also go back and emphasize the point that in 30 years there has been a dramatic reduction in the Defense Department's role as a sponsor of basic and applied research. It is now down to about 10 or 11 percent of the total Federal effort, as I note on page 3, and I think there is almost no chance that one could imagine this doubling over the next decade.

So, if you put that as an upper bound, we might be talking about as much as 20 percent of the total Federal effort supporting basic and applied research coming from Defense. It is really hard for me to believe that that would be regarded as an unreasonable situa-

tion. Obviously, the Defense Department has to defend its budget and have good projects, but in terms of one way of thinking about long-range implications, it seems to me quantitatively unlikely it will rise nearly to the level that it was 20 or 30 years ago.

Second, Mr. Chairman, in page 4 I review some of the well-known statistics about the total national funding in comparison to total defense R&D funding. I would like to remind you of some data that neither of the earlier two witnesses this morning specializing in defense matters at the moment mentioned. During the boom years, from 1958 roughly to 1972, in constant 1958 prices, defense R&D declined from about $5.7 billion to about $5.5 billion while the rest of the Federal spending tripled in real dollars or almost tripled from around $5 billion to between $13 and $14 billion.

So, this trend is long standing and the reemergence is, in a certain way, a misleading way to label what is, in fact, going on, because there has been a downward trend very steady now for 30 years. What we may see looking back from the year 2000 is that this was a fluctuation in the mideighties that goes back a few percentage points but not really significant in what seems to be a long-term secular trend.

On pages 5 and 6, Mr. Chairman, I try to ask the question that I think you were getting at and a very deep question it is: what will happen to the national technical work force and to the civilian economy more generally as defense R&D rises somewhat, even if it only rises a little as it seems to me to be likely the case?

There is not clear-cut evidence on that. You and the congressional support agencies undoubtedly will gather more than a lonely administrator in the boondocks of Manhattan can gather, but I did look at some of the literature. It looks fairly clinching that there is no real clear-cut sustained competition when it comes to technical manpower. In fact, generally speaking, what has happened in every one of the boom and bust periods over the last 30 years is within just a few years after defense R&D spending rises with only that lag, it creates its own technological manpower.

The signals are given very clearly to the scientific and engineering work force, and more people get into the fields that are being called upon. There is very little evidence from economists who differ very greatly in their political and ideological perspectives when they look at the data, they see very little clear-cut competition.

When it comes to impacts on the civilian economy broadly, clearly you can argue that there are major opportunity costs. I remind the staff and any members who are not familiar with it, there is a very good book written by Murray Weidenbaum in the early seventies about this point—what are the opportunity costs of defense spending generally, and defense R&D spending in particular.

There are clearly some opportunity costs, but again the case is not clinching that you can find specific science policies, to go back to that theme, Mr. Chairman, that could be modified to take account clearly of these civilian impacts.

Let me mention two points which are clear implications, however, about which there is no debate, in my judgment, about the reemergence of DOD. One is that there is going to be more debate

about defense R&D. As we draw more people into this community, and we are seeing that almost every day in the newspapers now—software for SDI being a conspicuous example—there will certainly be more debate. And that absolutely coincides over the last three or four decades with rises and falls in defense spending and other social attitudes, such as the Vietnam era.

A second point is the, I believe, rapidly rising tensions about flows of technical information, a theme that this committee has returned to, happily, from time to time over many years. I would just take a few phrases from the Corson panel report of the National Academy of Sciences:

> The best way to ensure long-term national security lies in a strategy of security by accomplishment. An essential ingredient of technological accomplishment is open and free scientific communication.

There is absolutely no doubt in my mind that as the Pentagon increases its defense R&D, it is going to find it harder to resolve the issues raised by this very seminal observation of the Corson panel, but it is very sound. What we have typically seen and is hinted at rather gently by Drs. Yonas and Cooper is that the technical part of the Pentagon favors this strategy. It is other policy officials in various agencies who don't favor it.

You find, I think, close to unanimity in the R&D community, Mr. Chairman, about this proposition.

In the midpart of my testimony, I run the risk of talking about concepts that members of this committee are likely to know more about than we. One of them is what do we mean by pluralism.

On page 26, Mr. Chairman, of your task force report and beginning on page 9 of my testimony, I take a stab at defining pluralism which has certainly become a cliche. We mostly think we know what it means, and I couldn't find, actually, a very reasonable stab at defining it, so I did try.

One of the points that quickly emerges when you start thinking about pluralism is that we claim that there are strengths in it because it disperses our strengths. That is in contrast in some sense to what Norm just argued. There is some good science in industry, and the question is how much.

On pages 19 and 20 and 21 of my testimony, I tried to collect some data that would answer this question. I agree with you, Mr. Chairman, and your task force agenda that we should try to be more quantitative than hand waving as we have typically been about these policy issues. One question I asked was where do Nobel Prize winners work? That is, where do the U.S. workers who win a Nobel Prize and are employed in the United States work? Some of this doesn't map identically with citizenship.

In that data at the bottom of page 19 through 1982—I apologize that this is 2, approaching 3, years out of date—I take a crack at that. It is interesting because it shows that roughly 10 to 12 percent of Nobel Prizes went to scientists in industry and Government laboratories. That is roughly the same proportion of basic research funding that went to scientists in Government and industry laboratories.

The conclusion I would draw—let us say a hypothesis to be looked at much more carefully—is that if funding continues for

long periods of time, and if it is directed in a way that all of the witnesses this morning have encouraged us to believe is necessary, that is, broad questions, deep questions, and stable funding, there is no reason why industry and Government laboratories can't do Nobel Prize winning caliber work. In fact, they have.

The prizes this year to scientists connected with ONR, one of whom still works there, I think, confirms this trend.

The next two questions I asked were, where do members of the National Academy of Sciences and National Academy of Engineering work? Again, it is not too surprising that members of the Academy tend to be in universities. That is, in fact, the home of basic science.

But it is interesting that again you get about 10 percent of the best scientists in the country as measured by this reasonably reliable indicator are working in industry and Government.

When you look at the NAE, the data change, naturally. Most of the best engineering is in industry, but not all of it by any means. In fact, only about 55 percent of the best engineers work in industry. The rest, who after all are elected by these industrial engineers who control the polling in the NAE, more than 35 percent are in universities and 5 percent or so in Government.

My hypothesis based on this data would be that it is reasonable to believe that you can do first rank science in a Government laboratory. To counter another stereotype, it seems to be reasonable to believe you can get distinguished, practical, innovative engineering out of a campus. Surprise, surprise.

That is the strength of pluralism, Mr. Chairman, I think, and a great power in the American system. To the degree that we further homogenize and classify and over-typify institutions, we will have lost one of the great powerful forces that we have from dispersing these strengths.

A final more conceptual point along that line and one that the committee and staff are well familiar with is the little diagram on page 23 that underscores with this one example from solid state physics, a field I know a little about or used to know, the enormous feeding back between technology and science. It is not correct to think about what this committee is up to in terms of a linear journalistic model of research feeds information which is then tidily taken care of by Norm's engineers and out comes a product with a business plan.

We all know that isn't true. What we don't focus on enough is at the fairly fundamental level the ways in which new tools enable new science, and new science feeds back into the new tools to do technology.

Let me skip, Mr. Chairman, because I know our time is limited to just highlighting two international points. I agree with Mr. Augustine that they are important, and I have mentioned four in my statement. I think at the moment I would really just like to highlight one, the social sciences. On page 28 of my testimony I have just a few paragraphs devoted to a subject that I realize you devoted several days of hearings to, but to my limited knowledge of what you have on your agenda of social sciences, you didn't emphasize this point.

That is the dearth of money and attention to social sciences pertinent to foreign policy and national security and arms control. For about 20 years, we have been running a national experiment with doing no social science research pertinent to foreign policy to the first order. This really originated because of a Defense Department program—one might say gaff or glitch or flap—about the so-called Project Camelot which was some studies beginning in Latin America about the sources of revolutionary movements. There is a book actually been written about this flap which reference I give you.

Since then, it has been almost impossible for DOD to support any basic research, unlike physics or astrophysics or computer software. It can't really touch this field very much. There is a little psychology that goes on in human factors engineering and vigilance before a radar scope, but no social science. The other agencies that clearly need that assistance or, in my view, might benefit from it, say, the State Department, either don't ask for the money or when they ask for it they don't get it.

This is an issue that is underappreciated because, in fact, much of our decisionmaking is not benefiting from the potential for some scholarship that could help it.

Let me close, Mr. Chairman, on one small skeptical note, and that is to doubt whether or not the pace of science and technology is necessarily all it is cracked up to be. In the last few paragraphs on pages 35 and 36 I remind the committee that the tricks, say, of genetic engineering are roughly 30 years old. They have been sharpened a great deal in the last decade by some profoundly new insights, but we first learned that DNA was the genetic material in 1944. Nobody paid much attention; it didn't help medicine and didn't produce biotechnology. It didn't produce boomlets on Wall Street near where I live, but it has been around for quite a while.

The first masers were working very well in the mid-1950's and quickly led to lasers. That whole technology is regarded, in a way correctly, as revolutionary, but it is really not clear that science moves quite as fast as in our more breathless hyperbole we would make it seem.

Thank you, Mr. Chairman.

Statement by Rodney W. Nichols before Science Policy Task Force

Committee on Science and Technology

House of Representatives

23 October 1985

1. Introduction

Thank you, Chairman Fuqua, for the honor of being invited to participate in your review of United States science policy. I am pleased to join these hearings entitled "Science in the Mission Agencies and Federal Laboratories" because I have thought and written about this subject from industrial, governmental, and academic perspectives. I also extend my congratulations to you, the Committee, and staff for undertaking such an ambitious inquiry. No matter what the long-term results may be, you have turned a cynical Washington aphorism on its head by raising the visibility of the important, not just the urgent.

Permit me to say a word first about my professional background. After university training in applied physics, I worked for seven years in industry on both civilian and military R&D, then served for almost five years in R&D management within the Office of the Secretary of Defense. For the past fifteen years I have been at The Rockefeller University, a center of basic research which has only a few DoD-sponsored projects. Mr. Chairman, although I have never been a full-time "policy scholar," I have been engaged as an investigator, administrator, and analyst within the domains you now are evaluating.

My testimony is divided into three sections: first, commentary on two questions posed in the September 6 invitation-letter from Chairman Fuqua; second, a more general discussion of the advantages and problems of pluralism in R&D, drawing upon draft material being prepared for a special 1986 issue of the quarterly journal Technology in Society, which will examine the pros and cons of forming a Federal Department of Science and Technology; and third, brief remarks on the areas identified in the Statement of Purpose for the SPTF Hearings during October 1985.

2. Specific Commentary on Chairman Fuqua's Questions

In Mr. Fuqua's 6 September 1985 letter inviting this statement, he asked:

(a) What are the long-range implications of the re-emergence of the Department of Defense as a major sponsor of basic and applied research?

(b) How does mission-agency support, as opposed to science-agency support, for research affect the types of research performed, the payoffs, the justifications of funding, the research performers, and infrastructure?

2.1 Reemergence of DoD in Research

The first question clearly requires an historical perspective. Before highlighting data on this point, however, and then discussing the implications, I should state my basic conclusion: growing DoD support

will be a great asset to the country's R&D institutions, if the process continues to respect the strong U.S. values in research that is high-quality, openly published, and usually investigator-initiated.

You already have received key data on the financial trends covering DoD's support of 6.1 and 6.2 programs. But two points (mentioned, for example, on October 2 by Teich, Carter, and Tegnelia) deserve emphasis. First, the "reemergence" of DoD as a major sponsor must be put into the historical series of the actual amounts and proportions. Defense funding was more than 50% of the total Federal support of research (6.1-type efforts) during the 1950's, dropped to roughly 25% of this total during the 1960's, and fell again to about 10% during the 1970's. It is now about 11% of the total Federal effort. Many significant trends are left out of such a stark summary, such as NASA's surge and NIH's growth. But the facts are clear: as the national R&D waves expanded greatly over the past 30 years, DoD's relative influence declined sharply in research.

Furthermore, it is unlikely that DoD's role would increase over the next decade to become, say, double its present proportion. Reasonable observers may differ on the merits of what was decided in the past, and on the probability or desirability of equally brisk changes over the next decade or two. But it is hardly extreme to devote 10% (even 20%) of our research resources -- and 1% (or 2%) of the DoD budget -- to national security. Indeed, it is a moderate and perhaps cautious approach, given the critical roles of technology in deterrence, intelligence, and arms control.

Second, the fields being supported by DoD are pertinent to long-range defense missions and ripe for advanced work leading to findings that will be broadly useful. Although the available aggregate data about this -- as shown in Teich's Tables 2 and 3 -- are not too clarifying, the

basic point is probably valid at any level of detail. What should be of concern is assuring the quality of work supported in these fields. To the exent that there is growing "micromanagement" from any quarter, often the best investigators will be driven away; this leads naturally to lower quality, and then even to lesser relevance because new "leads" may not be seen and tracked. Accordingly, DoD should be given fair latitude in its choice of fields. I will say a little more on this later from other perspectives.

Let us now extend the exploration of long-range implications by considering the broader national trends.

All of the distinguished "chief scientists" in OSD during the past 25 years have been keenly conscious of the varied interactions between Defense R&D and the national technical effort. Over this period, total military R&D spending has declined as a proportion of the total national R&D spending (from about 75% in 1955 to about 25% today) and it has declined as a proportion of the total national R&D funding to universities (from about 20% in 1960 to about 5% today).(1) Let us recall the "boom years" in R&D: from roughly 1958 to 1972, in constant 1958 prices, Defense R&D actually declined from $5.7 billion to $5.5 billion while all other national R&D (Federal and non-Federal) rose dramatically from $5.2 billion to $13.5 billion.(2)

Such trends are watched carefully in the Pentagon because the vigor of the overall national base is essential for the technological edge that political and military leaders have continued to count upon. The turnaround in these trends during the past few years should renew both the national and the Defense capabilities.

But what about the overall national economy? Did -- and would -- a large DoD role in basic and applied research affect the demand and supply

of scientists and engineers? Did -- and would -- such a "reemergence" of DoD affect the civilian industrial sectors? Unequivocal answers to these questions are not available, to the best of my knowledge. But they are good questions, and there is some evidence.

For technical personnel, the analyses strongly suggest that rising military R&D spending, through the usual market pulls with a lag of a few years, creates its own technological labor force.(3) Apparently there has been little, sustained, clear-cut competition between the defense and civilian sectors.(4) Indeed, for example, one leading national "high technology recruitment index" was 15% lower in March 1985 than in March 1980, confirming that only a few shortages exist now and that the recent 1-2% unemployment rate for engineers (low of 0.7% in 1966-68 and high of 2.9% in 1971) is not an artifact.(5)

As far as the civilian economic impacts of Defense R&D (or of general Defense spending) are concerned, the data I have checked are not convincing. Everyone knows that Defense-linked "high-tech" industries are important, e.g., semiconductors, electronics, telecommunications, computers, special manufacturing materials and robots, information-based services and firms of all kinds.(6) Military spending selectively pushes these and other newer technologies; and it often favors certain younger industries. Just as obvious, in principle, are the "opportunity costs," i.e., allocating public funds and devoting scarce talent to all of DoD's payroll, procurement, and R&D programs.(7) Yet pinning down those theoretical "opportunity costs," and being sure about the results of any reallocations to a major alternative purpose are not easy tasks.

In the overall economy, the military buildup that started in 1978 and extended through 1984 brought military spending from 5% to 6.7% of

the GNP (compared with 13% in 1953, 9% in 1968, and 6-7% in the early 1970's). Although changed tax rates and other trends are clearly important, higher military spending rates apparently account for a third of the size of the presently too high Federal deficit.(8)

Altogether, the plentiful literature on these complex economic subjects sheds little light on specific science policies that would make a large difference in either enhancing benefits, or suppressing difficulties, flowing from the interactions of increased Defense R&D within the general economy.

Before moving to Chairman Fuqua's second question, I want to add two remarks about ostensibly paradoxical tensions that will arise with substantially increased DoD support of basic and applied research.

One is that as more scientists and engineers become involved with the most advanced fields pertinent to defense, we can expect even more vociferous debates about both the R&D itself and the new systems that could be deployed as a result of the R&D. This will emerge naturally, as it did in PSAC and the DSB over past years, because some of the most talented leaders in research will become strong, independent critics of choices already made and of future options favored by the Pentagon.(9) Look at the professional literature of persuasive advocates and scathing skeptics about individual DoD R&D programs and about the economic and political consequences of these technical trends.(10) Look at the membership of policy-oriented groups such as the NAS's CISAC or the AAAS's CSACNS. You find that the most informed debaters have had considerable experience in the Defense R&D community. Yet for about 15 years, as defense funding declined relative to other areas and as the Vietnam era conditioned attitudes, there were comparatively fewer young people coming

into these fields of science pertinent to national security and arms control. With recent trends, the prospects are good for more debate on the R&D elements of decisions in defense policy.(11) Frankly, this is healthy as well as inevitable. But there will be days when the Pentagon may not be so happy.

My second point is that there will be a further increase in the tensions already evident about flows of technical information. I agree strongly with the deceptively simple, profound conclusion of the Corson Panel: "the best way to ensure long-term national security lies in a strategy of security by accomplishment, and an essential ingredient of technological accomplishment is open and free scientific communication."(12) To be sure, there are risks and caveats in such a strategy; and there are rugged problems in implementing it while enforcing our laws on espionage and promoting our trade. But the principle is so sound, so consistent with U.S. character, so fundamental to everything we know about what makes research thrive, that the temptations to "protect" our increased R&D results must be resisted in the future, as they usually have been in the past by the technical leaders in the Pentagon itself. This will be difficult for DoD's relationships with universities -- despite the welcome new funds for fellowships, instruments, and for research -- and yet it has always been a central feature of any "guidelines" for those university relationships.(13)

2.2 Effects of Mission-Agency Support

Mr. Fuqua's second question -- on the specific effects of a typical "mission-agency's" research support vis-a-vis a "science agency's support

-- is more complex. My comment here will be brief, since the next section provides a more complete statement on this matter. Consider this perspective: when a "mission-agency" supports the "R" in R&D and manages it well and coherently, the process inccrporates most of the attributes of "science agency" support that some observers believe are superior to (or at least different from) mission-agency practices in research administration.

Historically, the Defense research agencies (perhaps most notably ONR) have shown the insight, stylie, and patience needed to provide long-term funding for world-class science that pays off. Not every project, of course, was excellent; and not every grant was transparently relevant to Defense.

In DoD's 6.1 and 6.2, the goal was and is to press the limits of knowledge, develop human resources to provide advice on new technical problems seen in the field, and throw fresh perspectives on the full range of long-range options for pursuing old and changing missions.(14) NIH has fulfilled essentially these functions for HEW and HHS; it is doing research with disease and health care goals in clear view. While NSF ordinarily is regarded as the archetype of the "science agency," it also may be viewed as a truly national-mission-agency in most of the practices and results of the conventional mission-agencies. For instance, NSF's new research-oriented engineering initiatives surely keep an eye on U.S. trends in the international marketplace.

In short, when a mission-agency has a shrewd and balanced R&D program, part of that program will be in science. To pursue the science well, the agency and the projects must be in good standing with the scientific world.

3. Advantages and Problems of Pluralism in R&D: Arguments Favoring the Organization of Federal R&D Around Independent Missions

As noted in my introduction, this section draws upon a draft manuscript being prepared for a special 1986 issue of Technology in Society, a quarterly journal, which will be devoted to the pros and cons of proposals to form a Federal Department of Science and Technology. Although today's hearing focuses largely upon the research sponsored by DoD, the SPTF's reviews sweep more broadly and, in any case, the Defense R&D program is best placed in a larger context.

3.1 Defining Terms

Pluralism has become a cliche that points toward a rich texture of ideas, practices, and vested interests. Yet pluralism in U.S. R&D encompasses specific attributes. Sometimes, pluralism means just one part of the following definition and, at other times, the term signals the entire set. A definition might include:

(a) generally, the idea that there are multiple Federal and private sources (or sponsors) of R&D; i.e., several major agencies with large R&D efforts that include in-house technical staffs and laboratories along with outside grants and/or contracts to academic and industrial groups;

(b) more specifically, in most fields, the existence of multiple sponsors at a significant scale of research and development; e.g., NSF, DoD, and DoE sponsoring materials science and engineering; NIH, NSF, and DA supporting molecular genetics and biotechnology; and both DoD and NASA

funding advanced engineering studies of the aerodynamics of new vehicles;

(c) the concept that each Federal agency pursuing its operating missions has an R&D unit carrying out a substantial program of basic work, e.g., Commerce through the NBS, Agriculture through the ARS, HHS through NIH, and Defense through DARPA and the OXR's;

(d) from the standpoint of an investigator, the existence of opportunities to gain truly independent reviews of a novel idea (or of a rejected proposal) so that the decision of one potential sponsor does not eliminate the possibility of another open competition; and

(e) from the standpoint of private, working-level organizations performing R&D, the availability of multiple governmental and private sponsors, e.g., an academic chemistry department receiving industrial funds, state government support, philanthropic aid, along with grants from ACS, NSF, DoD, and NASA; and this notion applies to corporations as well, say Texas Instruments carrying out R&D contracts for DoD as well as pursuing its long-range business goals with their own R&D investments from revenues on sales to commercial customers.

Taken together, these arrangements provide a hedge against fluctuations in the fashions and policies influencing any lines of R&D support. More sharply put, they avoid a "science czar," or an "establishment," controlled by the Federal government.

A full-blown pluralistic system depends upon a high level of sustained R&D. It runs the risks of some redundancy when sponsors overlap their support -- surely at the research end of the spectrum, where there are many, small projects underway through many sponsors. By doing so, it gains the long-run advantages of giving all missions a window on re-

search.

Pluralism also protects against the inherent frailty, even occasional ignorance, of decisions by research managers. It aims, in principle, to strengthen the broad swath of R&D by being aware of how unpredictable are the origins of great ideas; and how unpredictable are the consequences of results that first seem mere curiosities. Thus, some funds go to all good ideas in order to ensure that the few seen later to be the best have had a chance.

The U.S. system of pluralism, the product of a wealthy country with a self-confident approach to science serving national goals, has worked well. It is the envy of the world. Only a combination of strong forces could challenge it. We now see three such forces. First, large Federal deficits tempt both the executive and legislative branches to reexamine "discretionary spending" -- i.e., the programs left after statutory spending such as Social Security -- and R&D is always a large fraction of this "controllable" amount. Moreover, the deficits elicit worries about "potential duplication," always an issue with R&D carried out in a decentralized fashion.

Second, other powerfully industrialized nations challenge our trade by orchestrating their public/private initiatives in R&D with a more centralized style. So the U.S. naturally considers the option of Washington-dominated "industrial policies" that would target R&D.

Finally, the national R&D resource-allocation process recently seems almost too competitive. It involves state and local governments competing for high-technology economic assets; hard-strapped universities struggling for revenues and impatient with a "Matthew Effect" in big-time research ("the rich get richer"); and individual investigators and fields

frustratingly trying to compete for their share of a research pie that grows slowly.

Despite these new strains on the foundations of pluralism, it still functions. And it depends above all on the Federal Government's "model" of how R&D functions in the country.

3.2 Rationale for Federal Roles: Fundamental Premises

The rationale for large Federal investments in science and technology has been remarkably consistent over the post-World War II era. This rationale has been articulated, with little dissent, by leaders in government, industry, and universities.(15) The upshot is that science is so important to the nation that only the Federal government can assure the scale and continuity of funding required for the varied national purposes. Justifications always stop well short of asserting that Uncle Sam should be the primary user of the results of R&D -- except in defense and, until recently, in space. The Federal rationale takes account of the marketplace.

Beginning with Vannevar Bush, this "marketplace" of interest to Federal R&D policymakers is a large notion spanning many elements of the private sector.(16) It must track the supply and demand for technically trained individuals from high school graduates to postdoctoral fellows. It must consider whether, and how, to renew mature industries facing strong international competition. It is always trying to accelerate the pace of technology transfer in order to enable entirely new industries to grow quickly and provide new jobs. It aims to strengthen the scientific

foundations for regulatory decisions serving the public welfare. It tries to apply modern science to prevent and cure diseases while being economical in the uses of known therapies. And on and on. In sorting out these myriad elements, what are the underlying premises of national (not just Federal) R&D?

Elementary premises are hard to "prove." But it is clarifying to state, explain and rationalize them. The three premises formulated here seem to reflect the beliefs of the majority of working scientists and engineers as well as policy-making officials in Washington.

The first premise is that mission-oriented research exists. Terminology gives trouble here immediately because some observers regard this premise as inherently contradictory. Wouldn't strongly mission-oriented work naturally be so applied that it would border on being "development?" If so, it would not be research. Moreover, the idea of "directing" basic research always provokes contention. Yet we also know how difficult it is to characterize excellent research as either "basic" or "applied."

There are many examples of successful mission-oriented research. The situations always became clearer in hindsight. The physical and engineering sciences, in fact, frequently have thrived on a close coupling -- virtually a blend -- of fundamental work and specific applications. More about this later. In the biological and medical sciences, too, the coupling has been close; although modern biomedical scientists are not as used to thinking about the issues involved.

The core of this premise is that the problems involved in achieving a specific long-range mission--from a government agency's point of view, or a corporation's view--sometimes must be expressed in such fundamental

terms that only basic research is likely to solve them. That kind of research is not necessarily less basic, or less pure, than comparably long-range but ostensibly more curiosity-driven scientific efforts.

Mission-oriented research works best when the goal is clear and fairly broad, not fuzzy and narrowly conceived. The time-frame for measuring success ordinarily is long and the sponsor does not insist impatiently on specific results to be achieved at short intervals. Yet the periodic quality-controls on the individuals in research must be authentic, open, and severe. The effort receives stable funding until either the desired results are achieved or new paths are encouraged as more productive.

Often, such research proceeds best at a university. But there are splendid examples of successful mission-oriented basic research in governmental and industrial laboratories. In any case, the Federal government is the only patron with sufficient staying power to fulfill this premise, especially with respect to diverse national goals pursued concurrently.

The second premise is that economic incentives are powerful. This may be evident to any industrial audience. Yet the idea is worth emphasizing in debates about how to organize R&D designed to foster greater innovation and productivity. Market mechanisms can promote, and surely need not degrade, both the quality and pace of the research community. Higher salaries, profits, royalties, consulting fees, and other rewards, when based upon merit, are all desirable. Too often, though, economic incentives are viewed with suspicion whenever public and private funding have common goals, as in defense or health. Market dynamics become essential to drive raw scientific advances toward economically meaningful

technological success. A glance at other countries around the world is sufficient to show how inefficiently R&D links with production unless economic incentives activate the linking process.

However, Federal support of R&D--i.e., public funding of early explorations, without a great range of economic incentives--also is essential in many (not all) fields and for many specific major projects. The reason, of course, is that there are also powerful economic disincentives to the private funding of high-risk, high-gain research. Frequently, an individual corporate investor would not gain enough in research to justify the risks. For example, few chemical and pharmaceutical companies invested in fundamental molecular biology during the 1960s; but NIH and NSF steadily built the base on which firms now safely stand.

Another classic case is the Federal funding of the fields leading to the remarkable increases in performance/price ratios for computers, based in part upon the Federal support of progress in electronic materials. The market soon assured sufficient incentives for sustained R&D. While Federal R&D funding continues to be needed in basic electronics, it might be less critical if international competition (mostly from countries with robust economic incentives for private firms) had not emerged so dramatically and did not involve such high levels of a combination of governmental and commercial investments.

A third elementary premise is that mutual interests build partnerships. Problems of collaboration among universities, industry, and government are not caused generally by a profound incompatibility (or an inherently adversarial relationship) between the R&D components of the sectors. If they were, laws and contractual negotiations--with due respect to Congress and counsel--could not solve them. Yes, there are

complex issues of patents and profits for industry and its partners. Yes, there are shifting social and scientific fashions for the patrons among the Federal mission-agencies. Such complex issues and Washington cross-currents do get contentious. But Washington cannot legislate greater creativity nor mandate specific coalitions for R&D. Laws and negotiations only smooth the way for what investigators and their institutions, in practice, judge to be healthy collaborations on a case-by-case basis.

This premise does not imply, Polyannaishly, that the various patrons and performers of R&D usually have identical goals, for that is not the case now and probably never will be. Yet there will be certain overlapping purposes and complementary motives. For example, universities may be prepared to wait a few weeks in publishing a paper emerging from corporate-sponsored research if the delay leads to a patent that may produce royalties; the underlying freedom to publish is not violated gravely by such a short delay.

There will also be divergent views and competing purposes. For instance, informed observers in Congress may differ on whether certain DoD-funded basic research, no matter how excellent, ever will yield utilitarian value for a soldier; but DoD scientists and university investigators may have mutual (and partly different) reasons for pursuing the effort. Each sector must be clear, of course, about its distinct principles and mission. Campuses must be open while corporations frequently are not. Federal agencies are accountable each year to Congress while universities see their research priorities in terms of decades. Federal agencies and universities also must have an informed sensitivity to commercial goals, accounting for the cost and risk of research in relation

to general business cycles. The test is whether, on balance, mutual interests spread broadly enough. If they do, then the parties adjust to each other's interests and unify their comparative advantages to achieve the goals in mission-oriented R&D.

A Federal agency has to decide, for example, what areas of basic research fit its long-range mission. Then the agency can invite a university investigator (or several) whose research aims match the agency's aims to form a liaison consistent with incentives that match the investigator's style and the investigator's institutional policies. The agency also must build adequate in-house scientific competence or it cannot chart its long-range aims with sufficient cogency to be confident about, much less manage, the mutual scientific interests to be served by the effort. The same pattern, of course, applies to corporations.

The Federal government has a unique responsibility to facilitate knowledge of R&D trends and promote communications at all levels in the private and public sectors. If this is done well, the three premises can be expressed in national efforts that succeed. What causes trouble are the revolutionary waves that often emerge either from R&D (e.g., VLSI or rDNA) or from the economic environment (e.g., the new trade problems internationally). These waves cause organizational strains that distract participants from proven practices. Just as in politics, where "a revolution is not a dinner party," organizing for technological change is rough.

Today, scientific and commercial competitions are tough, the social stakes high, and the Federal choices wrenching. Yet the three premises of our historical pluralism remain valid.

3.3 Historical Patterns: Dispersed Strengths

To understand the historical patterns, let us examine the dispersed strengths caused by the pluralism in mission-oriented research. One introductory point is that there is a history of the subject.(17) It encompasses the evolution of vaccines and lasers, of farm equipment and computing machines, of innovations along Route 128 and in Silicon Valley, and from before the 19th century through the entire 20th century. The historical strands involve individual scientists and theoretically inclined inventors interacting from and within the research community -- via diverse paths -- with engineers and the technological community associated in major markets. Many recent debates about governmental-corporate-academic links in R&D ignore the patterns and lessons of this history, probably at our peril.

From the late 1950s to the early 1970s, most academic investigators became complacent with growing Federal funding for basic research. For other reasons, the industrial R&D world also was content to let Uncle Sam fund most of the basic research. So university-industry links weakened. In parallel, during much of the past thirty years, no one paid consistent attention to the declining quality in scientific and mathematical education in elementary and secondary schools. Generally, then, despite a briefly energetic response to the shock of Sputnik, the country was coasting in its R&D, confident about what seemed unchallengable leadership in theory and practice, in intellectual vim and commercial vigor.

With overconfidence was bred a drift into seeing institutional stereotypes and tidy compartments of roles in R&D: research at universities

sponsored by Uncle Sam, development in industry, and a blithe faith in links being made whenever needed by a never-ending supply of well-trained personnel. This syndrome seems to have been particularly strong, although rarely expressed so crudely, among those benefiting most from the booming years of the mid-1960's. Now we are trying to work our way out of the limitations that these stereotypes imposed on the views of industry, government, and academe about each other.

Instead of these stereotypes of highly differentiated roles, what has been best in U.S. pluralism is the dispersal of strengths in R&D. This has enabled good linkages, high mobility of ideas and people, and flexibility in organizations responding to changing needs. Three propositions will sharpen this abstract theme. First, there is good science in industry and government. Second, there is a capability for effective invention at universities and in government. Third, there are many essential interactions between technology and science. Consider a few perspectives on these points.

To get at the issue of science in industry and government, we might check all Nobel Prizes to U.S. scientists (i.e., the sites of work, not citizenship) awarded in physics, chemistry, and medicine.(18)

Figure 1

U.S. Nobel Prize Winners in
Physics, Chemistry and Medicine
(1901-82)

University	Industry	Government	Other	Total
107 (85%)	9 (7%)	5 (4%)	5 (4%)	126

A total of 14 Nobel Prizes, or about 11%, went to industrial and governmental scientists. That is roughly proportional to the total funding, over this history, for basic research in those sectors. In other countries, scientific work is carried out more frequently in govenmental and "other" institutions.(19) These data cover only up to 1982; but the ONR scientists who shared the 1985 Nobel Prize in Chemistry confirm the trend.

This gross index suggests that where serious basic research persists over long periods in industrial and governmental units, it can produce world-class science of the quality that the Nobel Prizes are designed to recognize. Moreover, since selecting Nobel Prizes is a small lottery in some sense -- i.e., few, if any, mediocre scientists ever get one, but there are also many superb scientists who do not -- other individuals of Nobel Prize-caliber are working in governmental and industrial laboratories.

Another interesting index is our U.S. "elite" scientific group, the National Academy of Sciences. Here is a compilation of all members of the National Academy of Sciences, a total of about 1500, broken out by institutional sector.(20)

Figure 2

National Academy of Sciences

Institutional Affiliations (1985)

University	Industry	Government	Other
1170 (77%)	88 (6%)	88 (6%)	170 (11%)

Again, the total combined percentage from government and industry is about 12%, roughly proportional to the funds devoted to basic research inside the industrial and governmental agencies. Remember that since academics dominate the self-perpetuating election process in the NAS, the leading university scientists are voting for these fine investigators employed in industry and by government.

Lastly, consider data for the roughly 1200 members of the "elite" National Academy of Engineering.

Figure 3

National Academy of Engineering

Institutional Affiliations (1985)

University	Industry	Government	Other
461 (37%)	668 (55%)	59 (5%)	35 (3%)

For this group, the numbers naturally shift toward the largest fraction, 55%, coming from industry where most engineering and development goes on. The point here is that there is considerable high quality engineering at universities and governmental groups. Judged by peers in engineering, most of whom come from industry, almost half of the best engineers in the country are not employed by industry. This statistic suggests that campuses and governmental technical installations have good capabilities for distinguished engineering, which may be critical for significant invention, innovation, and the diffusion of "practical" ideas.

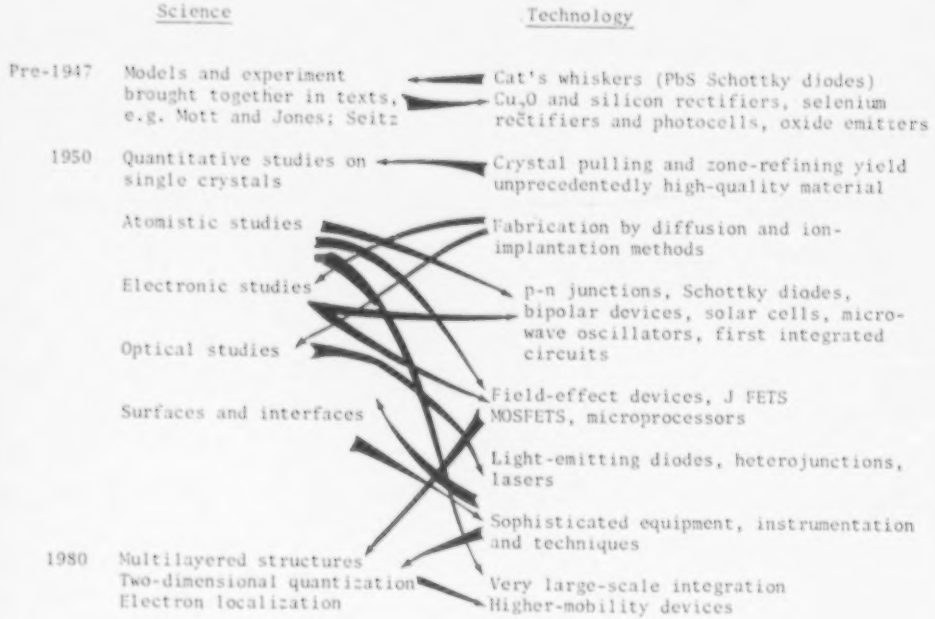
Another too-often-underrated proposition is the goal of fostering

creative feedbacks between science and technology. An excellent case is the history of solid-state physics.

From the late 1930s to 1980, viewed by a leading solid-state physicist who dissected the interactions between science and technology, this diagram of the 40-year period of astounding progress in semiconductors and related fields shows the power of interactions and dispersed strengths among the R&D institutions.(21) Often, we see, interactions do not follow the journalistically simplified linear model: basic research leading to new knowledge, then to an idea for practical applications, into detailed development, and finally to production and marketing. Instead, the arrows go in all directions. Some interactions happen rapidly, some take decades. In fact, roughly the same number of insights feed out of technology into science, as feed into technology from science. For example, the development of new ways to lay down molecular layers on crystals opened up new conceptual vistas; and theoretical insights led directly to the technological innovations embodied in scores of solid state devices.

As the diagram also shows, the modern story begins with two remarkable textbooks. They were seminal and had, in their way, great commercial importance as well as academic influence. One written by Frederick Seitz -- on solid state theory and experiment -- was the textbook that most professionals who work in the semiconductor industry and are, say, over the age of 40, used as their foundation when they were going to graduate school, often with governmental fellowships under the remarkable G.I. Bill. No surprise in that anecdote. It is just one more reminder of the importance of a powerful synthesis of fundamental ideas, particularly when the educational system is working and pluralism is fostered.

Synergism between physics and semiconductor technology



Science
Technology
Pre-1947
Models and experiment brought together in texts, e.g. Mott and Jones; Seitz
Cat's whiskers (PbS Schottky diodes)
Cu2O and silicon rectifiers, selenium rectifiers and photocells, oxide emitters
1950
Quantitative studies on single crystals
Crystal pulling and zone-refining yield unprecedentedly high-quality material
Atomistic studies
Electronic studies
Optical studies
Surfaces and interfaces
Fabrication by diffusion and ion-implantation methods
p-n junctions, Schottky diodes, bipolar devices, solar cells, microwave oscillators, first integrated circuits
Field-effect devices, J FETS MOSFETS, microprocessors
Light-emitting diodes, heterojunctions, lasers
Sophisticated equipment, instrumentation and techniques
1980
Multilayered structures
Two-dimensional quantization
Electron localization
Very large-scale integration
Higher-mobility devices

T. H. Geballe
Physics Today
November 1981

This pattern of interactions between science and technology is also seen in the biomedical sciences. It is hard to find, for example, even a remote laboratory today in molecular genetics without sensitive instruments for separating and purifying cellular constituents. These instruments have made it feasible to pose deep, researchable questions that were almost unimaginable a decade ago. Commercial products are being spawned directly on biological research frontiers that became reachable only with the aid of Federal support to establish the underpinning for these new technologies.

The underlying theme of these observations on dispersing our strengths among the R&D institutions and sectors is that an individual Federal agency can best orchestrate both short-range and long-range R&D efforts when it takes advantage of (rather than delimits) the diverse expertise distributed among all three sectors. Encouraging mobility and competition -- with some stable funding -- takes advantage of each sector's traditional strengths. Yet if a mega-agency attempted to do this simultaneously for all or most of the social goals served by science and technology -- from space to commercial standards -- there would be an inevitable tendency to classify, stereotype, and homogenize the roles of institutions.

3.4 Federal Patronage: Fashions and Complexity

With this complexity comes the untidy pluralism of Federal roles in managing R&D. It means multiple Federal R&D styles and occasionally even inconsistent programs. We have had, it must be conceded, some fragmented

policies over the past generation from that great patron of science, Uncle Sam.(22)

Overall, as we know, agencies across the government differ in their traditions and strategies for supporting research. On balance, that has been healthy, while we could afford it. The Department of Defense helped to "colonize" crucial modern fields such as geophysics, electronics, meteorology, and satellites; later, DoD changed its priorities for some of these areas. Recently, the DoD stepped up to help meet the nation's need for improved instrumentation in universities. NIH probably has the clearest tradition of sustained mission-oriented basic research. Yet the institutes are named for diseases. That is no accident, for the names reflect what is politically necessary and socially useful; while most of the research that NIH actually supports is relatively fundamental, a long way from the doctor's office. The National Science Foundation has certain major independent roles and it often has a "gap-filling role," i.e., helping those scientific fields in which, for whatever reasons, there are good scientists working while the fields temporarily are not either popular or mandatory for the mission-oriented agencies. Agriculture, Commerce, NASA, State, EPA -- each has had a unique history with gaps, successes, and failures in R&D. The fabric of desirable continuity has been frayed by changing fashions.

Lest this seem so far to be a convincing argument for centralization -- at least in science and education, if not in technology -- we should consider the complexity from the vantage point of the Federal purposes in R&D as a whole.

For one thing, it is usually the individual missions that provide the best case for why R&D is needed. As an example, in agriculture

today, the promise of plant molecular biology becomes the driving rationale for an increase in total agricultural R&D. This added funding for molecular biology is not being traded off against support for the health-related research in similar basic projects.

Take an even more specific case, the Mansfield Amendment to the Defense Department's funding in 1969.(23) Although it was an obscure provision that only applied for one year, it seems to have been subtly important in the subsequent evolution of national science policy. With the force of the then-Majority Leader of the Senate, the Amendment said, in effect, that DoD could not support research unless it related directly to its mission. That mandate said: do little, if any, "basic" research. Ever since, many agencies apparently have been affected informally by that now-dead law, symbolizing Congressional misgivings about "basic" research (read, "possibly irrelevant" research) in the large mission-oriented agencies. But this effect would have been much more severe if there had been a single Department of Science facing a generalized injunction questioning all support of basic research.

Another issue is that there are, in practice, many national economic and political decisions that create fissures in the pluralistic R&D approaches of the Federal mission-agencies. Any single agency responsible for "science" could never command the resources to meet all of these needs. For instance, a decade or more ago, when budgetary restraints and high inflation compelled most Federal agencies to ignore the capital needs of universities, no one sponsor conceivably could have come up with the funds that cumulatively have become a $5-20 billion shortfall in the facilities and instruments required for academic research and education.(24) Another example is the current turmoil about which Federal

agencies will participate, and in what ways, in fostering and regulating the sciences that feed the biotechnologies serving health and agriculture. Other fields also pose special issues, such as energy, in which since the early 1970's Federal agencies have presided over enormous fluctuations in R&D funding among industrial groups, the national laboratories, and universities. Such fluctuations and gaps have not been conducive to a healthy, competitive pluralism and, instead, have produced inappropriate signals for technical personnel in the labor market and even waste of scarce R&D talent.

Yet these problems did not arise silently, nor were they ignored by senior scientists and engineers. They arose, instead, from front-page controversies and White House decisions over which a hypothetical Department of Science and Technology probably would have had little influence.

3.5 International Trends: Stressing National Organizations and Budgets

At several points in this statement allusions have been made to the new international stresses on the Federal agencies supporting R&D.

Most important today is the comprehensive international competition in trade-spanning commodities, products, and services, all ranging from low-to high-technology. For this race, our national problem is neither technology *per se* (in which we often lead) nor the Federal funds for technological improvements (which has been comparatively generous). Instead, there are other factors: the technical literacy and social discipline of our work force; relative international rates of productivity increases; Federal deficits; interest rates; exchange value of the

dollar; savings rates and capital availability; tax incentives; and, above all, the increasing sophistication of our trading partners and competitors. These deep-running, almost intractable issues are beyond the scope of this paper. Yet they helped to produce justifications for the recent, authoritative recommendation to form a Federal Department of Science and Technology.(25) In effect, it was argued that "orchestrating national R&D" is an easier, and possibly politically more acceptable, path than any other when aiming toward improvement in our trading positions. Although those justifications evidently have not been convincing enough to change the pluralistic patterns reviewed earlier here, international trends are growing more important for the future.

Three other issues are closely linked with the R&D community, and these I highlight briefly because they show certain problems in pluralism.

One is research in the social sciences pertinent to foreign policy and particularly to national security and economic trends. Although I am neither an expert on the history of this subject, nor on the individual fields involved, it is too seldom discussed candidly in the frame of what Federal R&D "ought" to do.

The largely forgotten flap in the late 1960's about Project Camelot, a DoD-funded study of the sources of revolutionary movements, exemplified a terrible dilemma in Federal sponsorship of internationally relevant social research.(26) Most agencies with a need for such knowledge do not have the resources to carry out the work; while DoD, with both the need and the resources, constantly bumps into understandable public and Congressional sensitivities about "militarizing" scholarship and the policies flowing from it. The corrosive domestic debates about how and why

we got into Vietnam worsened this dilemma. But the issue was there for many years before Vietnam. It remains as a peculiarly crippling example of the general tensions when power and knowledge converge.

Because the social sciences usually elicit greater Congressional attention than the physical sciences -- certainly on a per dollar basis -- whenever an agency gets into social research, it can expect debate. The consequence is that the Federal government's support of research is meager in those social sciences relevant to the always debatable choices in foreign policy, national security, and global socioeconomic trends such as terrorism.(27)

After a comparative boom in the late 1950's through the mid-1960's, academic centers of social science were virtually starved out of existence for most of the 1970's and into the early 1980's. Sensitive studies of the Soviet Union, China, Middle East, Latin America, Asia, Africa — of almost any foreign area, related to cross-cutting international problems -- were forced to go for support almost entirely to private groups. Recently, both Federal and private support have increased slightly. But these new streams of funding are fragile.

To repeat, we know we need more than a small band of specialists on Japan, on the Soviet Politburo, on tribal loyalties in Africa, or regional military forces in China. Yet we do not have a robust Federal research effort. No agency wants to take the lead. The 1985 controversies about an openly disclosed CIA grant to a professor organizing a conference on Islamic Fundamentalism -- and about DoD inviting applications for support of regional studies -- remind us that it is still very difficult to start, much less maintain, such Federal programs.(28)

An international issue of a different kind is the R&D relevant to

developing countries. This is, in part, a subset of the problem just mentioned regarding sensitive social research; but it also extends to the comparatively less controversial task of analyzing economic data on the performance of individual countries in terms of development theories, social organization, and financial flows of aid, credit, and investment.

Even worse, there is the additional gap of effort on an enormous range of goals in the "hard" sciences and engineering: low-cost housing materials; urban water and transportation systems; malaria and schistosomiasis; the genetics of major food crops; population planning techniques -- the diverse issues that boil over in the so-called "third world" and that may be ameliorated, in part, by technologies developed and introduced humanely with the aid of the developed countries. This is such an extraordinary subject that I cannot do justice to any of its details here. Many specialized technical reviews are available and, over the past 25 years, many U.S. and international conferences have been held on both the scientific opportunities and the modes of global collaboration.(29)

The bureaucratic perspective of interest in this testimony is that these subjects always "fall through the cracks" in the Federal mission-agencies' approach to their R&D. The reason is simply put: Congressional sentiment, reflecting the public's attitude, strongly emphasizes domestic needs for science and technology. International problems that do not touch many of our citizens directly just do not command resources. Nonetheless, AID and the State Department bravely attempt to work on many of these matters. But they are second-guessed by critics and shackled by constraints from every quarter at all times. Whenever a regular mission-agency such as NIH or NBS or NSF starts a new program aimed at such an

international (i.e., mainly non-U.S.) problem, the budget is always in jeopardy. The international agencies such as UNESCO or FAO often are either politicized or inefficient, or both; and U.S. contributions to these agencies are thus also always in jeopardy. When R&D budgets are tight, even outstanding U.S. scientific programs pursued in an international context -- such as in geophysics or climatology -- may be overwhelmed by the domestic political impulses to avoid international investments with their administrative complications. The cumulative result of all this is a far less than optimal level of U.S. R&D in the international contexts for which the U.S. has both a moral responsibility and a large economic stake.

Turning to the fourth of these international themes, the DoD's 6.1 and 6.2 programs might be regarded in part as "leading indicators" of arms control issues that could emerge in the future. Even a casual reading of unclassified "arms control impact statements" reveals the tradeoffs among, restraints on, and lively pace of newer technologies interacting with decisions on national security/arms control policies.(30) The more policy-oriented assessments of the same issues -- such as the Defense RDT&E (and acquisition) program -- refer repeatedly to the impacts of research on choices for deployment and for negotiation (and vice versa).(31) Verification of urgently desired nuclear arms reductions, to cite the most obvious example, depends heavily upon advanced technical means (developed largely at universities and in industry) and upon the interpretations of highly trained analysts (most of whom are career employees of the in-house laboratories and FCRC's).(32)

Although it is not possible here to treat this subject fully I emphasize it because it is a clear example of the "internationalization"

of policy-making about the national R&D effort. Whether the arms control issue is non-proliferation of nuclear weapons to the third world or super-power talks on offensive missiles, the research community is involved. Whether the goal is avoiding technological surprise that could be destabilizing strategically, or pressing for NATO sharing in the procurement of more compatible systems that would strengthen the European deterrent, the programs and staff in basic and applied research play a role, sometimes minor and occasionally central.

Would a single Federal Department for Science and Technology likely deal effectively with these four matters? I doubt it. Comparative advantages in trade go well beyond the likely portfolio of the head of such a department. The social sciences have been vulnerable to disputes and budgetary slashes even where they seemed to fit easily, such as at the NIE and in the OEO. International R&D programs will not compete well against domestic R&D when so many U.S. scientists and engineers have so many projects and mouths to feed at home; and a new national agency would not assign its highest priority to such global tasks in any case. Arms control, and defense R&D, surely would not be the main concern of the hypothetical, more unified Federal science agency. Nonetheless, the hypothesis about a new department underscores at least these four striking issues in our pluralism organized around domestic missions -- and it becomes, therefore, a useful prod for thinking about how to improve our present system.

3.6 Final Note

The pluralistic model is consistent with Pasteur's aphorism: "There is only one science and the application of science, and these two activities are linked as the fruit is to the tree." Each tree needs independent nurturing, and each mission needs research.

4. Brief Responses on Five Areas in Statement of Purpose for SPTF Hearings on Science in the Mission Agencies and Federal Laboratories

In this section I offer selected responses with respect to the five broad areas identified as the focus for the October 1985 hearings.

Coordination and Management. The influence of external advisory groups to each agency -- and of the Federal Council in inter-agency efforts -- shows signs of being weaker than it should be for pluralism to work at its best. As outlined earlier, when an agency's basic research component is weak, ties to the independent technical community are attenuated. Furthermore, when all Federal R&D budgets are tight (as we know they were for most of the 1970's) and when new technical issues cut across traditional agency lines (as in uses of space), inter-agency cooperation is both more desirable and more difficult. Rarely, however, is "wasteful duplication" the issue; competition tends to reduce that to almost negligible proportions. Instead, the chronic issues are: Which good ideas should be supported? Which cogent advisor's recommendations make the most sense? Which agency should take the lead? OSTP and OMB possess the clout to bring clear concepts and decisive proposals into these matters, and they often have done so through new priorities.(33)

Extramural Relationships and Infrastructure. The classical consid-

erations in Federal R&D management -- orchestrating people, facilities, communications, cooperation, and stable funding while taking account of all performers -- have not always been expressed fully over the past 15 years. This occurred largely because the earlier era of rapidly rising budgets made it too easy to trim and trim during the more recent year-to-year squeezes. We paid too little attention to the accumulating deficits in the infrastructure. The mission-agencies often publicized the implications of the trends; but resources were thin, and decisions often were expedients. A national experiment with abolishing the White House science office didn't help matters. The inexorably rising costs of instrumentation needed for each investigator made matters worse. Now, finally, widespread political attention focuses on the problems as a whole. Solutions will evolve slowly in terms of overall budgetary limits; and 5-10 years probably will be needed under plausible budgetary scenarios.

Regulation-Driven Research. Many observers have noted the absence of a steady priority on R&D among the agencies for which this question is critical. The FDA poses different issues than the NIH's RAC for the appropriateness and scale of in-house laboratories and significant extramural research. In the DoD, the test-and-evaluation functions have often drawn upon in-house talent in ways that might be viewed as the functional equivalent of meeting "regulatory standards." Although I have never been immersed in this area, anecdotal evidence and intuition lead me to believe that a key issue is the long-running lack of funds and "high science" in many of the relevant fields (such as toxicology). This is amplified by the frequent clash of economic and ideological interests about the usually shaky foundations of any regulation's interpretation.

Federal Laboratories. The Packard Panel's penetrating observations and recommendations have been followed up through the agencies.(34) But "reform" is obviously not an easy task, as previous Administrations have seen. My limited experience in this area leads me to emphasize two fundamental points. First, R&D chiefs need clear purposes, within a budgetary limit, and then delegated authority on how best to assemble their resources to achieve these purposes. Too often, there are detailed controls on everything -- personnel, budgets, contracts, reports, and other variables -- all within rapidly shifting, or fuzzy, missions. Second, agency heads should employ more independent, "peer review" procedures for major promotions and other rewards to the R&D staffs. Quality and productivity in the better Federal laboratories tend to prove these elementary notions.

5. Concluding Remark

This Committee all too frequently hears the commonplace assertion that science and technology move quickly these days, so quickly that our institutions cannot cope with the pace. The assertion is common because it is true. But it also is misleading in some ways.

The origins of the spectacular principles and tricks of genetic engineering go back several decades; yet the markets for genetically engineered products remain very small, although the potential is great. The first operating masers, the precursor for lasers, were built 30 years ago; yet the related technologies are still correctly portrayed as "new" (even revolutionary) in many applications.

Similarly, it is not at all clear that our old institutions -- even in the admitted absence of a grand plan -- have been incapable of handling the pace of contemporary technical change. DARPA, for example, was created within DoD in 1958 and has enhanced the flexibility for mission-oriented defense R&D. The NIH, a "science-agency" in the minds of many, has invented useful quasi-regulatory roles that work well in guiding its interfaces with potentially risky laboratory work and with the ethics of clinical research.(35)

In short, the modern technical pace is too easily overstated, and the faster pace is no cause for institutional panic. Stability in international security probably continues to rest upon steadiness, including a vigorous R&D program designed to avoid surprises strategically and open up options for cost-effective modernization.(36)

In the preface to a 1959 monograph about electronic devices, there is the following quotation:

> "The earth is degenerating these days. Bribery and corruption abound. Children no longer mind parents. Every man wants to write a book, and it is evident that the end of the world is approaching fast."

An earlier appearance of this quotation was on an Assyrian tablet in 2800 B.C.

Mr. FUQUA. Thank you very much, Mr. Nichols.

Norm, on the question that you raised and certainly a very important question is about research conducted in colleges and universities. Where would basic research be conducted if it were not conducted—if we have a tilt too far to research in colleges and universities?

Let me paraphrase that a little bit by saying that one of the witnesses that I recall testified came from industry, Roland Schmidt, and is now Chairman of the National Science Board, testified that in colleges and universities—and particularly I am speaking of the graduate programs—is where we really train the scientists that you use in industry and the Government uses in the national labs and so forth. The way that we can stimulate that interest in conducting research and becoming involved in it is in the years that they are in college and doing graduate work.

If we didn't have that, where would it be conducted and would we train the scientists that we need for industry and the Government and so forth?

Mr. AUGUSTINE. I believe that universities are probably one of the most promising places to perform research as part of the training process.

Mr. FUQUA. I am speaking of basic and fundamental research, not necessarily applied.

Mr. AUGUSTINE. The point I guess I would like to leave with the committee is for what the DOD would call 6.1 and 6.2 research or applied research, the universities are an ideal place to perform that as long as it is not done at the expense of quality education. That was really the point I was trying to make.

Mr. FUQUA. That is a very important point.

Mr. AUGUSTINE. I do think that there are also the relationships with universities that can be set up where fine research can be done on a continuing and larger scale basis than perhaps the universities themselves can take on. That might be through research institutions that are somehow associated with universities, the word loosely as used in the agenda that your committee prepared. There are examples of such institutes that draw upon the faculty, that draw upon the graduate students, and they have full-time professional staffs.

I think some of those relationships with universities to complement the smaller programs the university itself can afford to embody, I think that is very promising.

In fairness, I should say I think it is possible to do good research in the industry. As I said, there are a few examples of it. The problem is not the quality of the people in industry. The problem is the lack of funds from the corporate sources itself that you dare to place in research and still be competitive.

That is a long answer to your question, but I think we have to count on the universities and institutions related to the universities to be the doers of research in this country, by and large.

Mr. FUQUA. How about some of the big science programs—let me address this to both of you—like high energy physics and nuclear physics such as what is conducted, say, at the Fermilab, discussion

of the Superconducting Super Collider, or atmospheric work that is being conducted at NCAR in Colorado, and a lot of these in the national energy labs or even in NASA, for that matter, where they are doing fundamental research in aeronautics or propulsion systems that probably extend beyond what industry could or could afford to do or even attempt to do, say, wind tunnels that are large, expensive, and every company doesn't feel like they can afford facilities of that type and is an appropriate role for the Government to be involved in some of those.

Mr. AUGUSTINE. I think those are good examples of where it is appropriate for the Government to be involved; namely, projects that require large teams of people and very costly facilities that nationally you just couldn't replicate over and over. I do believe, though, that as has been the model with NASA wind tunnels and the national labs, they make those available to industry and researchers from universities.

So, I don't believe there is any reason that use of those facilities has to be solely by people on the Government payroll. They can be people from industry or academia that come in and share those facilities and work together much along the model that we have seen in Japan. I think that would be a very constructive thing to do.

Mr. NICHOLS. I agree with you, Mr. Chairman, if what I think you are getting at is sort of hybrid institutions that bridge these stereotypic boundaries. There are examples in biology. The place where I work was started as the Rockefeller Institute for Medical Research. It granted no degrees and did quite nicely for 50 or 60 years doing basic research without being a university, without being industry.

There are a number of such examples. The most recent one that received a lot of publicity is called the Whitehead Institute which has a sort of an uneasy relationship with MIT in Cambridge and is led by David Baltimore, a distinguished molecular biologist. It is, in effect, a freestanding basic research institute and does not grant degrees.

I suspect that those innovations will be needed. If that is what you are getting at, I agree.

Mr. FUQUA. How do you think the Department of Defense can determine what basic research is relevant to its mission? I would ask that of both of you.

Mr. NICHOLS. I think my answer would be a little different than from what Yonas or Cooper said to you earlier. My hunch is that the best point of decision for that is at the level of the chief scientists, typically career chief scientists, in the three service research agencies and the people who are just below the Director of DARPA and frankly don't spend as much time on administrative matters and are closer to the technology.

The decisions about what is relevant inevitably involve debate because we have to go out 10 to 20 years, and there will certainly be no certain calculus about that.

Mr. AUGUSTINE. There is, as the committee well knows, a never-ending debate about whether there should be a requirement—pull for new technology based on what the operators need or should there be a technology—push based on what becomes available. There are two camps. I happen to believe that both are important.

I think the way the DOD can best approach the matter of prioritizing its research needs is to look at both those perspectives. First, what are the operational needs that we don't have? That then suggests technological capabilities one would like to have and suggests areas of research where you might explore.

On the other hand, I cited in my testimony any number of very important research breakthroughs that have occurred by people not looking for those particular breakthroughs but just because they were performing fine research in significant areas. So, I think one also has to have a parallel program where you work in areas of some promise but basically just go and do basic science, and you explore and you see what comes out of them. Sometimes, nothing comes out; sometimes, something very major comes out.

I think we have to allow our scientists a fair amount of latitude in what they do in the area of basic research, whether we are dealing with the Department of Defense or elsewhere.

Administratively, how you do that, I guess I would say, you do it with as little bureaucracy and guidance as required and make the decisions in the laboratories, not in the Pentagon.

Mr. FUQUA. Mr. Brown?

Mr. BROWN. Mr. Chairman, let me pass for the time being and go to Mr. Volkmer and Mr. Lewis.

Mr. FUQUA. Mr. Lewis?

Mr. LEWIS. No, thank you, Mr. Chairman.

Mr. FUQUA. Mr. Volkmer?

Mr. VOLKMER. I have no questions, Mr. Chairman.

Mr. BROWN. Mr. Augustine, you had a couple of statements in your prepared text that intrigued me a little bit. On page 6, you say very strongly that the DOD research—I am sure we are talking basic research—should be performed for the one and only purpose that it contributes to providing for the Nation's military security and should be supported to the degree commensurate with the risk one wishes to accept in the area of national security, which is a rather provocative statement because the degree of risk is a highly immeasurable kind of thing. Yet, you are dedicated in your allegiance to the need for healthy funding for basic research.

We have gone through this debate many times. It was a debate with regard to the relevance of basic research to DOD missions that led to the Mansfield amendment, as I am sure you recall. It is in the nature of basic research that it is pretty hard to determine whether or not it is going to have a direct contribution to a defense system.

How do we resolve that problem other than, of course, following the good judgment of the proper people which I am sure both of you would agree is important? Is there any way that we can do a better job of quantifying or setting boundaries on this question of support for basic research and how we can relate it to precise or even imprecise DOD needs?

Mr. AUGUSTINE. It is a very profound question. I have often heard in my career, particularly when I was with the Defense Department, arguments that we should spend more on defense this year because it will help stimulate the economy or because it will produce social benefits of some type.

Mr. BROWN. And you want to get away from that, obviously.

Mr. AUGUSTINE. I really do. I think that if you want to, you should perform in the DOD just that part of research and just those things that help with national defense. If the goal is to stimulate the economy or to perform in research in general, let me say, go do it somewhere else. Let the Defense Department concentrate on defense.

It produces a very tough judgmental question for the management, and that is how much should you spend on defense, particularly in the area of research. As you point out, you often don't know when you are doing the research whether it is for defense or whether it is for something else, and there are a lot of good examples, computer industry, communications satellites, and so on.

It gets to be an issue of how much risk you want to take, and we do take risks every day. Certainly, there would be less risk from the defense standpoint if the Congress were to increase the defense budget further. There is also a price to the Nation of doing that, and I am afraid I have nothing better to offer than that it is a judgment of qualified people as to how much risk you take as you increase or you reduce the defense budget, whether it be for research or otherwise.

I would say that within the defense R&D program, I believe and always have believed that the research budget should get first priority. It is No. 1. The reason for that is fairly straightforward. If you change the procurement budget by 10 percent, you probably change the operating capability of the forces by 10 percent. If you cut the research budget to the point you miss the Stealth airplane or the nuclear weapon or the longbow or the stirrup or whatever through history, you may change the capability of the forces by an order or magnitude.

I guess there is a Laffer curve in here that says if you put all your money into research, you have nothing to fight with and that is not the answer either. That is what makes it so tough to manage.

Mr. BROWN [acting chairman]. It becomes essentially a political judgment. Of course, you have mentioned some examples of where defense supported research made substantial nondefense contributions, computers, communications satellites, lasers, many others. But it is sometimes easier to get funding for research in the Defense Department than it is for research which is assumed to have a civilian application which, particularly today, we tend to say should be done by the private industry that would benefit from it.

That is the part that bothers me. We have some projects right now, for example, to take a recent one, the proposed research program on a hypervelocity spacecraft. There is undoubted military benefits from having that. Yet, there are tremendous civilian commercial applications from that.

It becomes a political judgment as to what you should do, first, the basic research—and there are some areas still requiring basic research—and then the applied research and exploratory development aspects of it. We are looking for guidance as to how we can better resolve that, but it is very difficult to perceive.

Mr. NICHOLS. I think you are certainly right that it becomes essentially a political or social judgment at the margin, but there are

quantitative indicators. We are not completely at sea, as you well know, Congressman Brown.

To perceive the defense mission as a high-technology mission loosely analogous to a high-technology industry and the high-technology firms, it wouldn't be amazing to have 10 percent of total sales spent on R&D. That is about where we are in the defense budget. Since you might expect that the Defense Department, since there is no other customer for its R&D, would have to fund more of the R part of R&D for the national mission, you might expect on that grounds alone just looking at indicators that the R part would be more R intensive in this monopoly, DOD, that is a high technology mission.

We are not a factor of 10 away from what that loose analogy would indicate.

Mr. BROWN. Gentlemen, I personally find your contributions to be extremely helpful and I am going to have to digest them for a period of time. I may have material for a number of speeches just out of your testimony.

We do have a rollcall on, and rather than hold you here, I think it would be best if we excused you and adjourned the task force. Thank you very much.

[Whereupon, at 12:15 p.m., the task force recessed, to reconvene on Thursday, October 24, 1985, at 9:30 a.m.]

57-279 O - 87 - 22

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

THURSDAY, OCTOBER 24, 1985

U.S. HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND TECHNOLOGY,
SCIENCE POLICY TASK FORCE,
Washington, DC.

The task force met, pursuant to notice, at 9:36 a.m., in room 2318, Rayburn House Office Building, Hon. Don Fuqua (chairman of the task force) presiding.

Present: Representatives Fuqua, Walgren, Lundine, Lujan, Packard, and Fawell.

Mr. WALGREN [acting chairman]. The task force will be in order.

Today's hearing is the last of six hearings that the task force has held on science in the mission agencies and the Federal laboratories. Today, we are going to try to focus on science policy in the Federal laboratories and also be exploring the issue of regulation-driven research.

The first witness, Dr. Lew Allen, is well known to the committee. As many of you also know, Dr. Allen is director of the Jet Propulsion Laboratory and a vice president of the California Institute of Technology. Prior to his appointment as director of the Jet Propulsion Laboratory in 1982, Dr. Allen held the rank of general in the U.S. Air Force and served as the Air Force Chief of Staff.

We are very pleased you could come, Dr. Allen, and join in this discussion with us. We appreciate your being a resource to this process and are glad you are here.

Let me ask if any of the other members would like to make any opening comments at the outset.

Mr. FUQUA. I would just like to welcome Dr. Allen and say that we are very pleased to have you and the other witnesses here today. As I mentioned to you, I apologize that I have to be in another place shortly, but I do thank you for your contribution on behalf of the task force. When we have your testimony, we will study it further.

Mr. WALGREN. With that, let me just invite you to proceed in whatever way you feel would underscore the points you would like to make. We appreciate having you and will make your written statement a part of the record and any written submission you would like to make will also be so. We invite you to discuss this subject with us.

[A biographical sketch of Dr. Allen follows:]

DR. LEW ALLEN, JR.

Dr. Lew Allen, Jr. is a vice president of the California Institute of Technology and the director of Jet Propulsion Laboratory. He assumed his duties Oct. 1, 1982.

Dr. Allen retired June 30, 1982, as Air Force Chief of Staff and a member of the Joint Chiefs of Staff. In the Air Force he held the rank of general.

He was born Sept. 30, 1925, raised in Gainsville, TX and graduated from the U.S. Military Academy at West Point in 1946 with a bachelor of science degree and a commission as a second lieutenant. He served as a pilot in the Strategic Air Command until 1950 when he entered the University of Illinois. There he received a master of science degree in 1952 and a doctorate in physics in 1954. Dr. Allen was then assigned to the Atomic Energy Commission's Los Alamos Scientific Laboratory as a physicist.

From 1957 to 1961 he was assigned science adviser to the Physics Division of the Air Force Special Weapons Center. And in 1961 he was assigned to the Office of the Secretary of Defense, Space Technology Office, in the Directorate of Research and Engineering, Washington, D.C.

From June 1965 to February 1973, he was assigned to the Office of the Secretary of the Air Force where he served in both Los Angeles and Washington in duties relating to military space systems, and in June 1969 became director. In April 1971 he became director of special projects, with additional duty as deputy commander for satellite programs, Space and Missile Systems Organization.

After serving briefly in the Air Force Systems Command at Andrews Air Force Base, Md., he was appointed in March 1973 as deputy to the Director of Central Intelligence for the Intelligence Community in Washington, D.C. In August 1977 he was named commander of Air Force Systems Command.

General Allen served as the vice chief of staff, U.S. Air Force, from April 1978 until he assumed his duties as Air Force Chief of Staff in July 1978.

STATEMENT OF DR. LEW ALLEN, JR., DIRECTOR, JET PROPULSION LABORATORY, CALIFORNIA INSTITUTE OF TECHNOLOGY, PASADENA, CA

Dr. ALLEN. Mr. Chairman, I am pleased to be here.

I realize that your inquiries relate to the broad science policies of the country, but I think that my contribution may be best to describe a particular mode in which the Government does research, and that is the one with which I am the most familiar, and that is how research is done by NASA using JPL. That will lead to some observations that I hope will be of some more general interest to you.

JPL is a NASA center. It is one of the nine NASA centers. It is the only one that is not a civil service center. We are a part of Caltech. All of the work that is done is performed under a single contract between NASA and Caltech. It is performed in Government-owned facilities. Therefore, JPL is what is technically known as a "Federally Funded Research and Development Center" where NASA is the sponsoring institution.

The contract is the document which specifies our mission and the conditions under which we may do work for other Government agencies. NASA assures the accountability of the appropriated funds that are provided and conducts, among many other reviews, an annual detailed performance evaluation.

This arrangement, I believe, has yielded excellent results over the years.

Our primary mission is the conduct of missions to explore the planets of our solar system. We also conduct other missions for NASA as they are assigned, and about 25 percent of our effort is for other Government agencies as approved by NASA. That is mostly Department of Defense these days.

The planetary missions are for science. The science objectives and strategies are formulated by the National Academy of Sciences. NASA uses boards and committees of external scientists to formulate plans to accomplish these objectives within budgetary guidance provided by NASA.

The scientific investigators for the missions are primarily university scientists, and that is by policy. JPL has internally a competent group of scientists who provide a minimum and necessary capability for the performance of our missions, but they must receive their support from NASA as a result of the peer review of proposals that they make.

JPL has no capital account and no pool of sustaining funds such as the RPM funds of the other centers. Our employees have no tenure, and if their work is not supported, they are discharged. This system, in practice, works well. It certainly deters complacency, and it motivates excellence.

Although our mission is space science, we are primarily an engineering lab with a characteristic of a full range of space system capabilities in-house, a doing laboratory. In general, over the years, we have had one major project that is the full range of the spacecraft system that is performed in-house, and then all others are contracted to industry. That is in order to ensure that we remain smart buyers and do not become too divorced from all of the skills that are required to execute space missions. In that sense, we are different from the other centers in that our ratio of in-house work and the extent of the in-house work is substantially greater.

NASA is a mission agency, but our mission is science. I think that planetary exploration has been a sound national investment, but that is not a U.S. judgment alone. The Soviets launch about twice as many spacecraft to the planets as do we. ESA, the European organization, and Japan are making major contributions and growing these days.

This particular arrangement has been good for Caltech. It has complemented the very basic research emphasis on the campus with a practical engineering emphasis at JPL. Students are attracted to Caltech by the proximity and relationship with JPL that ensures, to some degree, against Caltech acquiring an ivory tower attitude among its faculty as they pursue the fairly esoteric and basic research capabilities which are characteristic of the campus.

The close ties to the campus have provided benefits to JPL. They have provided a quality control for JPL. The ties to the campus have appeal to our employees. There is an intimacy of the relationship between JPL and the campus that is substantially greater than that that exists, for example, at Los Alamos and Livermore with respect to the University of California.

There are several faculty committees that review our work, and there is a committee of the board of trustees that pays particular attention to the activities at JPL.

The Packard report which has been discussed with your task force emphasizes a number of matters with which I agree. Some of these have been formalized in the OPM document dealing with FFRDC's and we are in compliance with those both in letter and in spirit.

One thing his report emphasized was that the laboratories need adequate flexibility in order to pursue rapidly innovative ideas. NASA provides JPL about 0.5 percent of the budget in terms of discretionary funds, that is, monies which can be used during the year to pursue particular items of research without the bureaucratic processes being required. That is up substantially from what it has been previously, and for that, I am pleased. But that is still small by comparison with other laboratories and what I think is sound judgment. There is a very considerable lack of flexibility that is inhibiting and does delay innovative research. There are many opportunities to pursue items which take too long.

We have taken increased work for Defense in the last few years. That work is constrained to about 20 percent of the total of our effort. Ten years ago, about 20 percent of our effort was for the Department of Energy and alternative energy sources, but that has shifted to Defense.

I think this work is appropriate. We can make a useful contribution, and much of the technology which DOD supports at JPL is very advanced and will later benefit NASA missions.

We do some classified work. Caltech allows none on the campus, and we must keep JPL generally open by the policies of Caltech. But the classified work that we do segregated at the laboratory is not a problem as far as I am concerned.

However, I am quite concerned about the present tendencies to control unclassified publications. The President's order recently has eased some of those concerns, but there remains considerable apprehension over what I believe are most dangerous trends in the country.

Our space missions are taking on more and more an international character, and I think that is highly desirable and will increase, and JPL is deeply involved in international missions of a number of different varieties.

We have very good people at JPL. We pay competitive salaries. I would like to note particularly to you that the average salary for scientists and engineers is almost exactly the same at JPL as it is at the civil service centers. Therefore, it is the flexibility which differs and gives us the opportunity to get, I believe, a substantially higher grade of employee. Our employees don't have any assured employment, as I said before. Yet, we are a very attractive place to work.

Other speakers have told you about difficulties with the civil service system and with contracting procedures for research. I believe that our experience shows that there can be a very cost effective, responsive, and fully accountable research operation without those inhibitions.

Mr. Chairman, with those brief remarks, I would be pleased to answer whatever questions you might have.

[The prepared statement of Dr. Allen follows:]

STATEMENT OF

DR. LEW ALLEN

DIRECTOR

JET PROPULSION LABORATORY

CALIFORNIA INSTITUTE OF TECHNOLOGY

before the

UNITED STATES HOUSE OF REPRESENTATIVES

COMMITTEE ON SCIENCE AND TECHNOLOGY

SCIENCE POLICY TASK FORCE

October 24, 1985

Mr. Chairman and Distinguished Members of the Committee:

Thank you for the opportunity to give testimony to your Committee's Science Policy Task Force panel on "Science in the Mission Agencies and Federal Laboratories". I will discuss scientific activities and related policies at the Jet Propulsion Laboratory (JPL). Since some of you may be unfamiliar with JPL, I will give you a little history and background information.

JPL was a key player at the very outset of the space age more than a quarter-century ago. The Laboratory, then a research and development facility conducting guided missile work for the U.S. Army, had the opportunity to undertake the development of Explorer I, the first American satellite. Outfitted with Dr. James Van Allen's Geiger counters, Explorer I certified a technological revolution triggered only four months earlier by the USSR's Sputnik I. While taking the initial measurements in January 1958 that discovered the existence of the Earth's radiation belts, Explorer I laid the foundation for the scientific investigation of the universe. Before the year was out, President Eisenhower reassigned JPL to the newly-created National Aeronautics and Space Administration.

Relying strongly on its Army experience with guided missiles and the Explorer spacecraft, the Laboratory became the NASA center principally responsible for the scientific exploration of the moon and planets. The Ranger and Surveyor lunar projects, Mariner missions to Mars, Venus and Mercury, the Vikings to Mars, and the Voyager missions to Jupiter and Saturn are among JPL's most significant accomplishments.

Solar system exploration by the U.S. reached a peak of achievement with the Voyager 2 Saturn encounter in August 1981 and capped a decade which included two Mars landings, three Mars orbiting missions, a Venus lander and orbiter, three close passes by Mercury with the same spacecraft, four missions through the Jupiter system and three to Saturn. Some of these spacecraft still endure. Pioneer Venus continues to operate in orbit at Venus. Pioneers 10 and 11 and Voyager 1 are heading out of the solar system and any or all of them may determine the yet-unknown location where the sun's influence ends and true interstellar space begins. Three months from today Voyager 2 will reach its closest point to Uranus. Early next month, the spacecraft will begin its far encounter observations of the planet. If it continues to operate as well as now, Voyager 2 will investigate Neptune in 1989.

Our next flight mission at the Laboratory is Galileo, scheduled for launch next May and designed to conduct a comprehensive investigation of Jupiter and its satellites. The Galileo spacecraft is comprised of an instrumented probe to penetrate the planet's atmosphere and an orbiter to examine the Jovian system for two years. The remarkable results of the Voyagers at Jupiter and the capability of Galileo lead us to believe that this mission will be the most productive planetary science enterprise ever attempted.

At JPL, we have a staff of 5000, about 58% of which are engineers and scientists, a quarter of them with Ph.D. degrees. JPL is operated by the California Institute of Technology (Caltech) in Pasadena under contract to NASA, our primary and institutional sponsor. JPL functions as a NASA center but, as a part of Caltech, operates within the general framework of Caltech policies. I will later describe some important differences between us and the NASA civil service centers that arise from our Caltech connection. We are a "Federally Funded Research and Development Center" (FFRDC) as defined by the OMB's Office of Federal Procurement Policy in OFPP Policy Letter 84-1; we are in compliance with the letter and intent of this and related policies and laws designed to ensure that FFRDCs perform work appropriate to them and are not used to bypass the requirement for competitive procurement. The contractual agreement between NASA and Caltech defines JPL's mission and role in NASA and the conditions under which we may perform work for non-NASA agencies.

JPL is the principal NASA center for the scientific exploration of the solar system and has significant responsibilities as well in support of NASA's applications program including, for example, the recent Shuttle flight of our micro-gravity experiment; the astrophysics program, typified by the highly successful Infrared Astronomy Satellite (IRAS) mission; and the earth sciences program, which began for JPL with the productive 1978 Seasat Project. The major emphasis of JPL's part of the NASA program is the planning and execution of exploratory applications and scientific flight missions in Earth orbit and throughout the solar system. These flight mission assignments involve a broad range of hardware and software engineering, scientific analysis, and management effort. We also support activities involving the planning, research and development, implementation, and operation of NASA's worldwide Deep Space Network and other facilities, information systems appropriate to the conduct of flight mission operations and data analysis.

Our focus is the execution of large, complex tasks involving the development and application of advanced technology through organized project team efforts. The true test of our quality and competence is found in the success of our projects, whether done in-house or by contracting with industry. JPL is, at heart, a hands-on doing organization. To maintain our ability to perform successfully such projects it is essential that we periodically have the experience of designing and integrating advanced spacecraft and instruments in-house. Such hands-on experience helps us to be "smart buyers" from industry when that is most economical. Our competence depends critically on having both engineers and scientists with the full range of experience from mission conception to the analysis of project results.

JPL scientists provide their expertise to JPL-managed flight missions, to flight experiments of JPL and others, and to the support of NASA in planning and formulation of their science program for the study of the Earth, space, bodies of the solar system, and the universe. They also perform their own research in terrestrial, planetary and space sciences. JPL directs its its research efforts to provide special emphasis to complement areas where universities are not strong, or where it is essential to have in-house competence to provide leadership for instrument developments or to provide candidates for Project Scientist positions and related supporting roles. Typically JPL scientists team up with other scientists, primarily from universities, to propose space flight experiments on a NASA mission.

JPL's principal scientific interests are in the areas of Earth/Planetary Atmospheres and Geoscience, Oceanography, Planetary Astronomy, Fields and Particles, Solar Physics, Astrophysics, and Space Processing. About 400 work-years were applied to these areas in FY85 divided roughly equally between Principal Investigators, flight experiments, and supporting activities.

Frank B. McDonald, NASA's Chief Scientist, has described to your Task Force on October 4, 1985, how NASA manages scientific research and plans its scientific programs. JPL space scientists are not block funded and must obtain funding for their proposals in open competition with others in the community in a peer-reviewed process where final decisions are made by NASA Headquarters offices. We believe that the process is even-handed and results in the selection of the highest quality and most relevant proposals. It has the further advantage to us of providing an independent judgement of the quality of our scientific staff.

The quality, dedication, enthusiasm and innovativeness of our staff are the key to our success. By a number of measures, JPL compares very favorably in productivity with other NASA centers. For example, the NASA Technology Utilization Program publishes TECH BRIEFS, its primary outlet for announcing and disseminating information on the development of technical innovations by NASA centers' staffs and their contractors. Between 1982 and 1985, JPL accounted for 42% of all independently evaluated and published Tech Briefs. This is indicative of both innovativeness of our staff and support of the NASA program designed to get such information into the hands of U.S. industry. Being a part of Caltech helps us to maintain high standards and to attract and retain the high caliber people we need. Caltech administration and faculty committees regularly review our programs and, on an individual level, there is interaction in areas of common interest. Both Caltech and NASA support our active efforts to develop and maintain effective collaborations with the larger community of space scientists. Many of our leading scientists and engineers hold joint appointments at Caltech and other neighboring universities and colleges. For educators at all grade levels, JPL has developed, with Los Angeles County, a Math and Science Teaching Resource Center to assist with teacher training and to provide the most up-to-date resources in the space sciences.

It is difficult to quantify the effect of our overall program on the number of scientific and engineering personnel in the nation, but many students and graduates have told us how they were inspired in their career choices by, for example, the Viking Mars landings and the Voyagers' photographs of Jupiter.

NASA supports a JPL Director's Discretionary Fund which has strongly encouraged JPL collaboration with universities. In addition NASA cost-shares, with Caltech, the Caltech President's Fund, which is designed to encourage Caltech faculty and other university scientists in initiating collaborative efforts with JPL staff.

In November 1982 David Packard and three other members of the White House Science Council's Federal Laboratory Review Panel (the "Packard Panel") visited JPL as part of their examination of national labs and their future. I was pleased by their evaluation of our staff and with their recommendations designed to strengthen the Federal laboratories and their contribution to society. I will comment on two of their recommendations.

I agree that civil service R&D laboratories would benefit from being allowed more flexibility of their personnel and hiring policies. While JPL's average salaries for engineers and scientists are comparable to those of NASA civil service laboratories, we have the significant advantages of being able to offer higher starting salaries for outstanding new graduates and of having a broader allowable range of merit-based salary increases. We also have a special career path for researchers which reduces their temptation to switch to management assignments for career advancement.

I strongly endorse the Packard Panel's recommendations regarding increased discretionary funds to lab directors because my experience is that such funds would be very productively employed. JPL is unlike NASA civil service centers where much of the staff is supported by block-funded Research and Program

Management funds. Each JPL employee charges time to specific job numbers. While this arrangement is sometimes precarious, on balance I find that it works to our advantage by increasing our responsiveness to our sponsor and by providing clarity of purpose. An unfortunate aspect is that I, as Laboratory Director, have very limited ability to support seed efforts that I believe to be important.

NASA increased the discretionary funds to JPL over the years since 1969 to the present level of just under 0.5% of the R&D funds we receive. These discretionary funds have been effective in strengthening interactions with university faculty and graduate students, in encouraging publication, and in leading to important sponsored follow-on work. Our survey of past discretionary fund expenditures indicates that, while two-thirds of the effort has been directed toward advanced scientific and engineering investigations directly related to our NASA program, about one-third of the funds were applied to investigating the application of advanced technology to civil/non-space programs. In 1985, I applied DDF funds to strengthen our joint efforts with the University of Arizona in the detection and imaging of extra solar systems. Because of limited discretionary funds, which must support both JPL and collaborator (burdened) salaries in addition to the usual costs, we were able to support only one-fourth of the proposals submitted. I know there are worthy innovative ideas waiting to be explored if funding levels are increased.

NASA, through the contract and Memorandum of Understanding with Caltech, has recognized the obligation of JPL, as a major national laboratory, to serve society by helping to solve important national problems where our special capabilities can make a significant contribution. We meet this obligation by devoting part of our effort to defense and civil programs which complement our work for NASA. In FY'82, 22% of our staff was so

employed; in FY'85, 25%. During that interval there was a significant decline in our work for DOE, accompanied by a sharp rise in DOD-sponsored efforts emphasizing advanced technology work in areas where NASA support had weakened. I anticipate that the level of non-NASA work will not increase and that the mix of sponsorship will continue to be responsive to national priorities.

Getting back to JPL's primary role for NASA, I remain optimistic about the future of planetary science and about the research opportunities for working scientists and for young people beginning or preparing to begin their careers in the field. The decline that the program underwent a few years ago is behind us now. The Congress responded by increasing NASA's budget line items for research and analysis and for mission operations and data analysis which support the activities of many researchers, in addition to members of the various flight teams.

Further impetus to the planetary program came in the recommendations of the NASA Advisory Council's Solar System Exploration Committee (SSEC) in 1982 for a new set of planetary missions consistent with the scientific strategies of the Space Science Board and realistically reflecting the changing fiscal climate. The SSEC recommended setting strict priorities for prospective missions, adoption of lower cost, innovative approaches to their implementation, and the integration of the program's interrelated elements -- research, operations and missions — into a coherent whole.

SSEC's core program, which could be sustained at an annual budget level of $300-325 million (FY84 $), assigned highest priority to the Venus Radar Mapper (VRM) mission. VRM was approved for a project start in FY'84 and will be launched in 1988. A new class of low-cost missions using already-developed Earth orbital satellites as the carrier spacecraft

was recommended for future exploration of the inner planets. The Mars Observer is the first of this class to be approved and began development in FY 85 for a planned launch in 1990.

The final flight element of the core program is a new planetary-class spacecraft called Mariner Mark II, conceived as a simple, modular spacecraft to be designed in-house at moderate cost for missions beyond Mars. SSEC recommended a comet rendezvous mission as the first of the Mariner Mark II series. Both the comet rendezvous mission and the spacecraft design are in the final stages of pre-project development at JPL.

I believe that the NASA planetary program is scientifically valid, balanced and affordable. We at JPL support it and are in the process of implementing it.

In summary, JPL is a FFRDC, a national laboratory, a NASA center and a university operation. We have a record of accomplishment and a status of excellence. Our sponsoring agency, NASA, has specified clearly our mission. NASA administers JPL through a single contract with Caltech and insures our proper accountibility for government-provided funds. NASA conducts detailed, annual overall performance evaluations of our effort and requires response to any needs for correction. I believe we continue to make significant contributions to the nation in a cost effective operation which places particular emphasis on scientific and technical excellence.

DISCUSSION

Mr. WALGREN. Thank you very much, Dr. Allen.

Let me understand a little more about the personnel because this is new to me and I was sort of trying to listen and think of some other points you made at the same time.

Your people are not civil service. Is that right?

Dr. ALLEN. That is correct. All of our employees are employees of Caltech?

Mr. WALGREN. Are they university employees then?

Dr. ALLEN. Yes.

Mr. WALGREN. So, the laboratory is itself not an integral part of Caltech.

Dr. ALLEN. No; we are an integral part of Caltech.

Mr. WALGREN. An integral part?

Dr. ALLEN. Yes.

Mr. WALGREN. And there is a working arrangement between Caltech and NASA as far as its direction in which the research goes?

Dr. ALLEN. The contract is between NASA and Caltech.

Mr. WALGREN. I see.

Dr. ALLEN. I am the Director of JPL and vice president of Caltech.

Mr. WALGREN. I see. Can you elaborate a little more on the discretionary funds available to you? You said you had 0.5 percent, that it was up substantially from what it used to be. What did it used to be and what would you like to see in this area?

Dr. ALLEN. It used to be $1 million a year, and it was increased to $2 million, and this year to $3 million, for which I am very pleased. Those funds are used at my discretion through a peer review process which I conduct in the laboratory to permit, for example, new scientists who have not been able to be established in obtaining support for their work yet to be supported; to pursue particularly innovative ideas that arise during the year; and to undertake new directions which is where I feel the laboratory needs to develop its skills and competence. For example, we have been pursuing with some emphasis with these discretionary funds work in advanced microelectronic devices, work that is very compatible with certain research that goes on in the laboratory and will lead, I believe, to substantially improved instrumentation capabilities for future NASA space missions.

Now, there is an additional fund which NASA provides to the president of Caltech which is a matching fund. That is, NASA provides some funds and Caltech provides funds. That is used primarily for campus research which will, in one way or another, involve JPL.

Mr. WALGREN. But the base fund you have is 0.5 percent of the total research?

Dr. ALLEN. Yes; our budget in fiscal 1985 closed out the year at about $650 million. I am provided for next year $3 million.

Mr. WALGREN. Can you compare that with any other laboratories?

Dr. ALLEN. Yes; I think Los Alamos and Livermore, for example, under DOE policies, end up with a portion of their basic programmatic activity, and I think that portion is on the order of 10 per-

cent which is available to the laboratory director for discretionary work.

Now, one needs to be careful about this term discretionary. For example, those funds at Los Alamos and Livermore are available clearly for work that is associated with the programs. It is audited and reviewed and judged by DOE, but it is not subject to prior detailed approval. DOE has a very nice arrangement with those laboratories to avoid prior micromanagement of these activities, and the laboratory director has a substantially greater sense of responsibility for what his scientists are doing in pursuing new activities than I feel that I do under the more limited discretionary funding arrangement.

Mr. WALGREN. Thank you. Let me recognize Mr. Lundine.

Mr. LUNDINE. This is a fascinating example of a partially Government-partially private operated laboratory. From your experience, would you think it would be advantageous if other laboratories were converted to Government owned, contractor operated?

Dr. ALLEN. I find that a very difficult question, because it turns out that almost all of the FFRDC's under this mode were created many years ago. One has the handicap of realizing it has worked well but not being quite sure as to the extent to which that should be started again.

For example, with regard to Los Alamos and Livermore, there is no question that the University of California management of those two laboratories has been, and continues to be, of great benefit to the country. But it would be very surprising if the University of California would undertake those arrangements if one asked that question now.

However, I do believe the record of these arrangements of the ones that I am most familiar with, Los Alamos, Livermore, JPL, the Applied Physics Laboratory at Johns Hopkins, and a few others, have been successful. Therefore, they represent a model that is worthy of careful consideration in the future.

Mr. LUNDINE. Your testimony indicated that NASA's discretionary funds to JPL are just under 0.5 percent of the R&D funds received. I think you testified also here this morning that Caltech professors serve as evaluators in part as to your work. What mechanisms do you have in place to evaluate the effectiveness of those funds expended?

Dr. ALLEN. I am required to report to NASA headquarters annually on the use of those funds and to report in detail on the work that was accomplished and the people who did it. So, that work is evaluated by NASA after the fact.

Mr. LUNDINE. And do you have any other internal evaluation?

Dr. ALLEN. Oh, yes; we have an internal peer review system which selects the work in the first place. My chief scientist happens to be in the hearing room this morning, and he leads the peer review activity which selects the projects which we will do under that discretionary account and judges their progress during the year.

Mr. LUNDINE. Thank you. Thank you, Mr. Chairman.

Mr. WALGREN. What is the greatest benefit of operating in the model or mode of your relationship with the university and the contractor that you would cite?

Dr. ALLEN. Well, there are certainly several. The first is a more flexible personnel policy, that is, the ability to hire, discharge, and pay salaries in accordance with the needs.

The second one is an ability to do contracting in a manner which, while it meets the formal requirements of the Government; that is, we do not take shortcuts in terms of procedures, is nevertheless free of many of the time consuming bureaucratic processes associated with the contracting. So, our research contracting can be done, I believe, more effectively and more speedily than at NASA headquarters without any loss in the rigor of the process.

The third is that there is no question in my mind that the intimate association with the Caltech campus provides an assurance of quality control and scientific excellence which I think has been reflected over the years in the performance of JPL.

Mr. WALGREN. Mr. Fawell?

Mr. FAWELL. Thank you. I apologize for not being here sooner.

Let me ask this question. You had indicated that you thought the University of California, if it were to be asked now to undertake its contractual obligations in operating Los Alamos or Livermore, would not do so as it did. Apparently, that is a long operation by the University of California. Why do you say that?

Dr. ALLEN. The University of California is required each 5 years to evaluate and then renew the contract. They have just gone through that process again here in recent months and decided to renew it.

However, if one looks at the discussions that go on within the University of California board of regents and the faculty and the leadership of the University as they discuss that, it seems clear to me that they regard this as an anomaly and a distraction from the fundamental purposes of research and teaching at the University and one which, if the history were not what it is, they would probably not undertake. However, the history is what it is, and the University has contributed to the security of the country in that management. Therefore, they continue to accept the responsibility of that stewardship.

Mr. FAWELL. Would you say that would be the same reaction, say, of the University of Chicago in reference to Argonne?

Dr. ALLEN. I am not really qualified to judge on Argonne.

Mr. FAWELL. How would you explain the difference between the arrangement, say, of the University of Chicago or, if you are not familiar with that, the University of California and its operations of Los Alamos and JPL? What is the difference?

Dr. ALLEN. In principle, they are quite similar. That is, the way the contractual arrangements are made and the responsibilities are quite similar.

The differences, of course, are really more in the practice. First of all, there is geography. We are 5 miles or thereabouts from the campus, whereas Los Alamos is a lot farther away from Berkeley.

The second one is that we do only a small portion of classified work which is segregated on the laboratory grounds and the laboratory, in general, is kept open since most of the work being for NASA is unclassified and is intended to be fully open to university researchers and students. Therefore, we work hard to ensure that what little classified work we do doesn't impede on that.

Clearly, Los Alamos and Livermore have greater restrictions, and it works the other way around. The university seeks to find mechanisms for university researchers to interact outside the fence, if you like, but with the scientists inside the fence.

So, those differences do restrict seriously the interactions between the university researchers at the campuses of the University of California and the two laboratories whereas they do not at JPL, and that interaction is far more active.

Mr. FAWELL. Thank you.

Mr. WALGREN. Thank you, Mr. Fawell.

You mentioned with respect to personnel and personnel policies and relationships that the salaries were comparable to——

Dr. ALLEN. The average salaries of scientists and engineers at JPL is almost exactly the same, according to a survey which NASA did recently, as the average salary of scientists and engineers at a NASA civil service center.

Mr. WALGREN. Are they directly comparable also to the Caltech salaries?

Dr. ALLEN. The campus salaries?

Mr. WALGREN. Yes.

Dr. ALLEN. That is a harder comparison to make, because in general the campus, of course, consists of faculty with tenure and salaries that are associated with tenured faculty. Therefore, our salaries tend to be more compared with the staff members on the campus who are smaller in number and tend to be more temporary in employment, that is, research associates and the like. So, in general, No. 1, we are required by the policies of comparability, that is, our salary structure at JPL is freed from certain detailed reviews by the OPM because we maintain a comparability between our salaries and the staff salaries at Caltech, but there are some differences.

Mr. WALGREN. What about turnover and discharge experience? Can you compare those with other Government laboratories—Government-owned laboratories like Oak Ridge or something like that?

Dr. ALLEN. Yes, and I think all of these numbers are more or less comparable, including those of the civil service centers. That is, even though I make this point that our employees do not have either tenure or any assured employment due to the nature of the contractual relationship, in fact, the turnover is fairly small. It runs in the 7- or 8-percent kind of range on the average. Some years, of course, if there is a decrease in the budget, it will be greater.

That number is, I think, more or less the same as the civil service centers and is about the same as the other FFRDC's operated by universities I am aware of. So, the two points that I really would like to emphasize to you from that is that the protectionist aspects of the civil service and the inhibitions on the salary structure in the civil service, in the final analysis, don't do much constructively, but they inhibit the system very greatly.

Our employees do not have protection, but they don't go out at a much higher rate than they do at a civil service center. We do not have constraints on our salaries in the same way at all, yet the average salary is not appreciably higher. So, it is clearly possible to have the same economies, the same low turnover rate at civil serv-

ice centers if one simply is granted the flexibility from the civil service system.

NASA is proposing such things at its civil service centers at the present time in accordance with initiatives that it is working out with the Office of Management and Budget as part of a project to improve productivity at the centers. I think these initiatives will be helpful to NASA.

Mr. WALGREN. Do you have any apprehension about Federal laboratories occupying a field that would be better reserved for universities in the research that they do in the institution itself?

Dr. ALLEN. Yes, sir. I think that is an important point and one that has to be guarded against all of the time. We take a great deal of care of that at JPL. We understand the policy in that matter quite well, and we recognize the need to ensure that we do not engage in inappropriate competition with universities. The policy is that the science research on the NASA missions will be done by university scientists.

It is necessary that we have scientific capability at JPL and that it needs to be an excellent capability, but it is to be limited. It is limited in those areas where universities may not be able to provide the competence—fields that are new or developing that have not developed in a university. We need certain project scientists to work intimately with the spacecraft designers, and they need to be in-house, and so on. There are a few of these requirements which we must have.

As I indicated, those few that we must have still must compete in the peer review process which NASA headquarters runs for their support.

Mr. WALGREN. There is a specific policy that the research shall be done by university scientists. Is that right?

Dr. ALLEN. Yes. That is correct.

Mr. WALGREN. That same policy wouldn't apply to other laboratories. Is it possible to generalize about how a Federal laboratory can not invade what might be agreed upon as a university role? I don't know whether I could define a university role for you, but aside from implementing apparently a direction that was developed whole cloth for JPL, thinking of Federal laboratories, Federal science effort more broadly, can you warn us to be limited in what we do within the Federal laboratories? Are there down-sides to that? Is there an overreaching tendency to want to expand into areas that would better be left to universities?

Dr. ALLEN. Yes, I think there is such a tendency. I think it simply must be guarded against at all times. It is hard to generalize. Again, going to Los Alamos and Livermore, you can't move that research, for the most part, out of Los Alamos and Livermore for classification reasons, and for the very highly specialized character of certain aspects of the research.

Nevertheless, the Government policy overall is that the basic research of the country should, in the overwhelming majority, be performed in the universities of the country, on the campuses of the universities, and that the places where the Federal Government does that at a Federal laboratory should be considered exceptions to that.

There are a number of required and appropriate exceptions, but they need to be monitored and ensure that they do not exceed what is, I think, a sound fundamental policy that basic research should be performed at the universities.

Mr. WALGREN. But the Federal laboratories are having to get into this more and more in that—my only measuring point would be the Bureau of Standards where we had obviously a solid function that had to be fully developed but were doing basic research which could also be done in universities. Yet, if we don't continue to have the complete function there, we would be missing something at some point.

Dr. ALLEN. Of course. There are good reasons for doing basic research in Government laboratories, but the policy should be that those reasons should be implemented with a notion that they should be minimum.

Mr. WALGREN. Mr. Packard?

Mr. PACKARD. Thank you, Mr. Chairman.

Do you think that other laboratories ought to operate more as a Government-oriented operation as yours is, or do you believe that you have specific assignments and characteristics that would justify having yours operate differently than most of the other national labs?

Dr. ALLEN. Again, I find it somewhat difficult to generalize, and I think the operation of JPL has been a very good one for the Government. If the situation arose where a similar appropriate circumstance could be implemented, then clearly I think that would be the best thing to do. I think there are significant advantages in the JPL kind of operation as compared with the civil service kind of operation.

Mr. PACKARD. Are there some disadvantages? Do you find some difficulty with JPL the way it is operating that you wish could be rectified?

Dr. ALLEN. My job is to rectify the difficulties at JPL, so certainly I work on that all the time. But those that are associated with its not being a civil service organization?

Mr. PACKARD. That is what I meant.

Dr. ALLEN. I am hard pressed to think of any. It is clear that from time to time, a non-Government employee, in the execution of the planning and the formulation of policy for a government body, is treated somewhat differently. That is, JPL, on occasion, is viewed by NASA headquarters as being somewhat different than their civil service employees.

In fact, that is minimal. JPL in the planning processes, in the different bureaucratic action processes of NASA headquarters, is treated in by far the majority of the cases equivalently with the civil service centers. Perhaps if all the other centers were not civil service centers, that would pose an awkwardness in that civil servants clearly have a preferred relationship in the executive branch for the execution of policies and contractual arrangements.

So, again, I find it hard to say that all centers should be operated out of the civil service mode. I guess the conclusion I come to is a little bit different, and the point I have been trying to make is that I think JPL proves that the inhibitions inherent in the civil service system and the bureaucratic constraints on the research contract-

ing process are not necessary, and that there is no reason why one couldn't have the flexibility and the responsiveness in the civil service laboratories that one can have at JPL by simply granting flexibilities with an assurance that the JPL operation provides that one will not lose control of the contractual operation nor see salaries escalate out of bounds.

Mr. PACKARD. I have no further questions. Thank you.

Mr. WALGREN. Thank you, Mr. Packard.

Mr. Lujan?

Mr. LUJAN. Thank you.

DOE runs all their laboratories on a GOCO basis, don't they?

Dr. ALLEN. As far as I know, yes, sir.

Mr. LUJAN. I can't think of any right off that aren't, and that has worked pretty well.

Dr. ALLEN. Yes, sir.

Mr. LUJAN. Yesterday's meeting brought out the fact that the GOCO's, at least in my estimation, were established to get away from all the civil service requirements of people having their tenure and moving people in and out as the needs changed. That was pointed out as one of the shortcomings of the civil service system.

You have had experience both in and out of the Government and the GOCO's. Do you think that we need to make some changes in the civil service system to be able to bring people in and out quickly into managerial positions? It was suggested, for example, that we set up some kind of a classification of maybe 3 years that somebody could be brought in without all the hassle of being nominated and having to put up with all the regulations. Do you think that would be beneficial?

Dr. ALLEN. Yes; I believe there are a number of changes which are needed in the civil service system for the purposes of research operations. NASA is in the process of formulating a set of those as a major initiative with the Office of Management and Budget, and they include the feature that you just mentioned.

Mr. LUJAN. In practice, does it happen that people move in and out of JPL, Livermore, all the different ones, or generally once somebody gets into one of those organizations is it a lifetime position, or do you change because of the changing needs?

Dr. ALLEN. The answer to that——

Mr. LUJAN. I mean, what is your turnover rate?

Dr. ALLEN. Our turnover rate is low, and JPL has, as a matter of fact, a number of employees who have been there for a very long time, as do Los Alamos and Livermore.

I really think that the point is that having that flexibility, having the nontenured, the nonassurance of employment, having to respond to fluctuating budget levels as these laboratories do, has not historically provided a churning situation at all. It has provided a stable environment.

But the flexibility, the knowledge of the employee that he can be removed, or transferred, or moved, or whatever at the management's decision if the needs require it is a fundamental difference. The attitudes are different. I believe the ability to keep qualified people there and to attract qualified people is fundamentally differ-

ent under that kind of an arrangement even though, in fact, the salaries are not higher nor is the turnover greater.

Mr. LUJAN. The actual practice—at least I keep very close track of Sandia and Los Alamos because those are my constituents and I don't want to see the employment level fluctuating—in actual practice, the GOCO's don't have very much fluctuation in funding levels, do they? Does JPL or is it pretty constant with maybe a little 5 or——

Dr. ALLEN. No, no; JPL has had more fluctuations than have Los Alamos and Livermore. We are a different kind of a laboratory in that we are more engineering oriented where Los Alamos is highly physics oriented, and we are funded to execute particular programs. So, our funding does fluctuate with the approval of a given program. For instance, our biggest on-going program now is Galileo to Jupiter. That is at a peak funding and a peak of personnel. So, we do have more fluctuations than do Los Alamos and Livermore.

There is a second situation with regard to JPL that is different than Los Alamos, and that is it is my judgment that JPL should not grow. There are several reasons for that. One is the small size of Caltech and, therefore, that places a constraint. The second reason is a geographic one. We really don't have much room to grow, and I don't think we should expand into other geographic locations.

Los Alamos has had a fairly steady growth over the years which is, as far as I can see, still continuing. So, there are those kind of differences. We have constraints on our employment, No. 1, and, No. 2, we fluctuate more than Los Alamos and Livermore. We have gone through periods where we have reduced the staff by a reasonable amount, amounts on the order of 10 percent. So, that is a difference.

But we can do it effectively, without loss of morale, and respond well to the needs of the Government under the flexibilities that we have.

Mr. LUJAN. Does Caltech leave you pretty much alone to run your show?

Dr. ALLEN. No.

Mr. LUJAN. As the director I would imagine—some directors have said we either like this or we don't like this because they collect their percentage and we do our thing——

Dr. ALLEN. No; there is a very significant distinction between Los Alamos and JPL with regard to the university.

Mr. LUJAN. I wasn't singling out Los Alamos. I don't want to say that one of their directors told me that. They have not, but directors in different Government laboratories have expressed that preference.

Dr. ALLEN. Over the years, the University of California has had a very modest influence, and appropriately so, on the management practices at Los Alamos. At JPL, the arrangement is substantially more intimate, due to proximity, due to the unclassified nature of the work at JPL, and just due to the tradition of the laboratory.

For instance, I am the first laboratory director who has not been a faculty member of longstanding at Caltech. We have a great many interactive appointments of one kind or another between the campus and the laboratory.

Mr. LUJAN. Do you mean in cooperative programs rather than in operating the whole facility?

Dr. ALLEN. Well, not in operating, I think, but cooperative of a number of kinds. For example, the principal investigator, the project scientist, on the Voyager mission is a Caltech professor. The principal investigator on the camera for the Hubble Space Telescope is a Caltech professor. So, there are a lot of those kinds of interactions which are very close. The chief scientist, at various times, has been a Caltech professor.

So, we have many very close interactive appointments, interactive arrangements. I participate in the management processes on the campus, and there are faculty committees that review various aspects of the work at the laboratory.

Mr. LUJAN. If you got some direction, of course, from the faculty committee, your responsiveness must be to NASA. Is that not correct? Rather than to Caltech?

Dr. ALLEN. The contract is clearly between NASA and Caltech. It is between NASA and Caltech. It is not JPL; it is Caltech. Therefore, it is clearly necessary for me to be responsive to both the direction of NASA and the policies of Caltech.

When those come into conflict, there can be an issue. There are issues of very small character that arise all the time. In some of the legal areas, for example, there are little differences in the procedures which NASA might like to see us follow and those which Caltech follows, and those are ironed out by negotiation.

Sometimes, these interactions are not all that pleasant. A faculty is not the most straightforward organization in the world to deal with. Therefore, sometimes the faculty expresses opinions about the work at JPL which I don't particulary like and don't agree with, but nevertheless, I think that arrangement, on balance, is a healthy one. It is a vibrant one, and it provides challenges to make it work smoothly.

Mr. LUJAN. With your long experience—just to sum up the thrust of the question—is it more advantageous or detrimental to have a GOCO type operation as opposed to a direct employee operation? If you had to do it one way or the other, which would you prefer? Where can the best results be obtained?

Dr. ALLEN. The university-operated laboratory.

Mr. LUJAN. Thank you, Mr. Chairman.

Dr. ALLEN. By the way, Mr. Lujan, just for your interest, I served a tour at Los Alamos. I am presently on the scientific and academic advisory committee to President Gardner for Los Alamos and Livermore, so I visit there periodically and have a great admiration for that laboratory. And I like to compare JPL with Los Alamos. I don't mean that in a——

Mr. LUJAN. Well, it would be more comparable with Sandia. It is more engineering-oriented.

Dr. ALLEN. It is perhaps a little more comparable with Sandia, but nevertheless, because I both admire and appreciate the work at Los Alamos, I find that Los Alamos and Livermore provide a certain set of standards which I think is useful to keep weighing the operations at JPL against and vice versa. I take to them suggestions now and then of the things that we do that they might emulate.

Mr. LUJAN. Thank you.

Mr. WALGREN. On behalf of the Task Force, we certainly do appreciate your being a resource to us, Dr. Allen. Thank you.

Dr. ALLEN. It is a pleasure to be here.

PANEL: REGULATION-DRIVEN RESEARCH

Mr. WALGREN. The next group of witnesses have been asked to discuss regulation driven research with us. This panel includes Dr. Joe Hendrie, Dr. Bernard Goldstein, and Thomas Jorling.

Dr. Hendrie is, by way of introduction, with the Brookhaven National Laboratory and is a former Commissioner of the Nuclear Regulatory Commission. Dr. Goldstein is a former Assistant Administrator of the U.S. Environmental Protection Agency and is presently Chairman of the Department of Environmental and Community Medicine at Rutgers Medical School. Mr. Jorling is also a former EPA Assistant Administrator for Water and Hazardous Materials and is presently a professor of environmental studies at Williams College.

Gentlemen, welcome to our discussion. Written statements will be incorporated in the record fully. Please feel free to underscore those points you feel you would like to emphasize and communicate them in whatever way you feel most effective.

Why don't we start and go through all your testimony, one after the other, and then we will come back for some discussion. In the order in which I introduced you, we will start with Dr. Hendrie.

STATEMENT OF DR. JOSEPH M. HENDRIE, BROOKHAVEN NATIONAL LABORATORY, LONG ISLAND, NY; AND FORMER COMMISSIONER, U.S. NUCLEAR REGULATORY COMMISSION

Dr. HENDRIE. Thank you very much, Mr. Chairman. It is an interesting experience to come back to the Halls of Congress and to see you all, but it is also a pleasure to find myself in this somewhat more congenial theater than has been the case.

Mr. WALGREN. I was going to say you are a lot more relaxed than your old Nuclear Regulatory Commission days.

Dr. HENDRIE. True enough, Mr. Walgren.

There were four questions addressed to this panel on regulatory directed research. The first was, "Should regulatory agencies maintain R&D programs or should their R&D be conducted by another agency or agencies? In other words, does it matter where in the bureaucracy regulation—related research lies?"

My answer is that it does, and it makes a lot of difference. The regulatory agency has to have control of the content and the schedule and the budget of the research if that research is to be responsive to the needs of the agency. It does matter where in the bureaucracy the control lies. If it is not with the regulatory research, the research will sooner or later wander away from those regulatory needs.

In my experience, it is no easy job to keep the researchers and their agency program officers pointed in the right direction, even when those program officers are in the same agency and the research is in effect controlled by the same agency. If the researchers

and the program officers report to a different agency, you sort of lose any hope of keeping them on track.

It is not that researchers and program officers are maliciously intended, you understand, but the research always opens fascinating new avenues on either side of the scheduled path—research opportunities that had not been suspected when scheduled work was started—and if the researchers and the program officers too are worth a tinker's damn, they will want to follow those avenues.

In a good regulatory research program, of course, there is flexibility provided so that some of those new avenues can be followed. But the agency managers have to watch out and see that the main effort doesn't suffer. That careful monitoring is not practical if the research program control is in another agency.

The other agency's program officers, soon or later, will convince themselves that they know better than the regulators what the regulators need, and then the research will begin to wander off the path, and the poor regulators will be left sending ineffectual memoranda of complaint and their information needs will go unattended.

The second question that was posed to the panel is, "How should regulatory agencies maintain quality science in the face of regulatory deadlines?"

My answer is, keep the science and the deadline separated. There is a basic incompatibility between science and regulatory work. Regulatory work is focused on the present—today's problems. It has a time horizon that is rarely longer than a month or two. Research takes several months just to define the technical areas that you are going to think about and move forward into research. So, research time horizons are years.

The solution is to contract the actual research to organizations that specialize in it. In the regulatory agency, you look for people who have a bent for science and good technical credentials and you put them in a research management section. You separate that section from the day-to-day crises and problems that the licensing and regulating people are dealing with. These people in the research management section then become the contracting agencies and program officers for the various programs of research that are contracted out to universities, Government and private research labs, scientific and technical organizations, and anybody else who may have the competence to deal with a particular area.

That separates the science from the regulatory deadlines and keeps them from confusing one another. The research management section in the agency and the individual program officers become an isolation device. They translate the regulatory issues into scientific and technical objectives that the researchers can address. At the other end of the work, they ought to interpret the research results in terms of regulatory needs.

The advantages of this system are considerable. In the first place, the agency gets much more scientific bang for the buck. It can place a given piece of work with an organization that specializes in that area, has unique facilities, perhaps world leaders in the research in that area. The agency thus piggy-backs on other and ongoing research in that area at that particular organization and benefits from a quality of people and the quality of equipment that the agency could not possibly have afforded as an in-house effort.

Second, the system keeps the research-types doing research and the regulator-types doing regulatory work. As a general rule, people with the right temperament for one don't do very well in the other.

Finally, the system creates a community of very smart people in the universities, in the laboratories, and in the research organizations who are knowledgeable about the regulatory agency's missions and programs. Those scientists and engineers are then a major resource for the agency. They can provide advice and reviews on assorted scientific and technical matters crucial to the agency, and they give the agency ready access to the larger community of scientists and engineers around the world.

The third question had to do with how a regulatory agency should translate questions framed by nonscientists into scientific questions that research can address.

The answer is that that is the job of the research management section in the regulatory agency. Sometimes, the translation is pretty easy because, at least in safety regulation, you find that the people in the licensing and regulatory staffs generally have good technical backgrounds and will understand the way in which to phrase the questions.

The hard problems come when you have to deal with a lay person who simply doesn't have the background to understand what sorts of things can be measured and answered in a well-defined way, and then the problem of the translation of the question into a research objective becomes more difficult and becomes an iterative process in which you have to go back and in part educate the questioner and in part iterate his question into a form so that it can be translated into a research objective.

Asking the right question, that is, getting the scientific and technical objectives of a piece of research correctly defined, is about half the battle. A diffuse or inaccurate definition will almost certainly lead to a diffuse or inaccurate result from the research in terms of the regulatory need. Sometimes, it may be necessary to do a not insubstantial piece of research in order to understand what the question really should be.

Mr. Chairman, the last question was, "How are scientific research results best translated into the regulatory arms of the agency?" The answer is with difficulty.

In my experience, it is not easy to get the regulatory-types to use the results of the research which not so long ago they were complaining desperately they needed. The reason is pretty clear.

The regulatory and licensing people live literally on a day-to-day basis. The problem comes up in a technical area. They need an answer. They complain that they don't have the answer. That starts the research program generation process going. But it may be years before the answer comes back out of the research. In the meantime, the regulatory and licensing people have to live this afternoon and tomorrow and next Monday. So, they have to go ahead and devise some solution, and it generally involves a very conservative interpretation that gets around the particular technical problem by, in effect, overshooting on the safety requirements.

Then, by the time the research comes back, the regulatory people have long since forgotten that this was a desperate issue with

them. They had this problem but it was a long time ago and the situation has moved on to a lot of other things in the meantime, and they are a little reluctant to go back in and dig up this thing which is not bothering them today or this afternoon or tomorrow and introduce the research results and readjust the regulatory requirements and integrate it into the general regulatory patter.

So, you can understand very well why there is a reluctance to incorporate the results of research. The answer just is that the agency management needs to be very firm and insist that new results on a consistent and orderly basis be introduced into the requirements.

That is essentially all I wanted to say, Mr. Chairman, except to note finally that it is a pleasure to find a panel of the Congress that isn't asking the question "Why does a regulatory agency need to do research at all?" It is real pleasure to find a group in the Congress and their staff who understand the answer to that question well enough so it doesn't even need to be on the list.

Thank you.

Mr. WALGREN. Even if they are lay people.

Dr. HENDRIE. Even if they are lay people. Well, I think you have heard enough about science and technology in the years on this committee so that all of you qualify for something considerably better than lay people.

Thank you, Mr. Chairman.

[The prepared statement of Dr. Hendrie follows:]

TESTIMONY OF

JOSEPH M. HENDRIE

Brookhaven National Laboratory
Upton, N.Y. 11973

before the

COMMITTEE ON SCIENCE AND TECHNOLOGY
U.S. HOUSE OF REPRESENTATIVES

at a hearing on

"Science in the Mission Agencies and Federal Laboratories"

October 24, 1985

Mr. Chairman, I commend you for holding this series of hearings on "Science in the Mission Agencies and Federal Laboratories." You have posed a number of searching questions to the many witnesses who have appeared here. I think the record of these hearings will be a most valuable reference source for policy decisions on research for a long time to come. I am pleased to have a part in these hearings and to have the opportunity today to offer a few remarks on research in the regulatory agencies.

I had better make clear at the beginning my background and prejudices. I have been a staff member at Brookhaven National Laboratory off and on for 30 years. I have a high regard for Brookhaven, and for the other National Laboratories in the Department of Energy system. In the years when I was away from Brookhaven, I worked for the Federal Government in the area of nuclear regulation. I served with the Atomic Energy Commission's regulatory staff in 1972-74 and on the Nuclear Regulatory Commission in 1977-81. Since returning to Brookhaven in 1981, I have been on a part-time basis, with the balance of my time devoted to my consulting practice. In that practice, my clients are utilities with nuclear plants. I have a lot of experience with science in nuclear regulation, as a

researcher, as a regulator, and through my current clients, as one of the regulated. My views are inevitably shaped by that experience, and by my firm belief that the NRC safety research program has been an outstanding success.

Mr. Chairman, you suggested four questions to this panel. The first is "Should regulatory agencies maintain R&D programs, or should their R&D be conducted by another agency or agencies? In other words, does it matter where in the bureaucracy regulation-related research lies?"

My answer is that for the safety-regulating agencies, at least, it is essential that they have R&D programs that they control. The regulatory agency need not carry out the research with its own personnel and, in fact, it should not, but control of the content, schedule, and budget of the research must rest with the agency if it is to be responsive to the needs and priorities of the agency. It does matter where in the bureaucracy the control over the research lies: if it is not with the regulatory agency, the research will sooner or later wander away from the regulators' needs.

In my experience, it is no easy job to keep the researchers and their agency program officers pointed in the right direction even when those program officers are in the same agency as the licensing and regulating staff. If the researchers and program officers reported to a different agency, there would be no hope of keeping them on track. It is not that researchers and program officers intend to go in other directions, but that the research always opens fascinating new avenues of investigation on either side of the scheduled path, research opprotunities that had not been suspected when the scheduled work was started. If the researchers, and the program officers too, are worth a tinker's dam as scientists, they will be unable to resist these new avenues.

In a good regulatory research program, there is some flexibility provided so that some of these new avenues can be followed. But the agency managers have

to keep careful watch to see that the main effort, the scheduled work, does not suffer. That careful monitoring is not practical if the research program control is in another agency. The other agency's program officers will convince themselves over time that they know what the regulators need better than the regulators do. Then the regulators are left sending ineffectual memoranda of complaint and their information needs go unattended.

Your second question, Mr. Chairman, is "How should regulatory agencies maintain quality science in the face of regulatory deadlines?"

My answer is that you have to keep the science and the deadlines separated. There is a basic incompatibility between science and regulatory work. Regulatory work is focused on the present, today's problems, with a time horizon rarely longer than several months. Research needs several months just to define the technical and scientific questions to be addressed; research time horizons are several years and often more.

The solution is to contract the actual research to organizations that specialize in research. In the regulatory agency, one finds (or recruits) some people with good scientific and technical credentials and an inclination toward research. These people are put in a research management section and are separated from the day-to-day crises and problems of the licensing and regulating sections. They become the contracting agents and program officers for the various programs of research that are contracted out to universities, government and private research laboratories, and scientific and technical organizations.

That separates the science and the regulatory deadlines and keeps them from confusing one another. The research management section in the agency and the individual program officers are the isolation device. They translate the regulatory issues into scientific and technical objectives that can be understood and addressed by the research organizations. At the other end of the work, they

interpret the research results in terms of the regulatory needs.

The advantages of this system are considerable. In the first place, the agency gets much more scientific "bang" for its buck. It can place a given piece of research with an organization that specializes in that kind of work, has unique research facilities, and world leaders in the area. The agency thus "piggy-backs" on other and on-going research in that area at the particular organization and benefits from research people and equipment that the agency could not possibly have afforded as an in-house effort.

Second, this system keeps the research-type people doing research and the regulator-type people regulating. Most top-flight research people simply don't have the temperments for licensing and regulatory work. And most people who can sustain and even enjoy the crisis atmosphere, the do-everything-yesterday pressures, and the sheer abuse of regulatory work simply don't make good research people.

Finally, the system creates a community of very smart people in the universities and laboratories and research organizations who are knowledgeable about the agency's mission and program. Those scientists and engineers are a major resource for the agency. They can provide advice and reviews on assorted scientific and technical matters crucial to the agency, and they give the agency ready access to the larger community of scientists and engineers around the world. On occasion, the odd researcher may even develop a taste for regulatory work and join the agency.

Your third question, Mr. Chairman, is "How should a regulatory agency translate questions framed by non-scientists into scientific questions that research can address?"

My answer is: Give the job to the agency's research management section. It is what they are supposed to be good at doing. Sometimes the translation will not

be too hard, especially if the question originates with the regulatory staff. The regulatory people in the agency may not be research scientists but they are familiar with the scientific and technical issues they have to deal with and most of them will have scientific or technical educations. So the regulators will tend to form their requests for information in a way that makes translation into research objectives relatively easy--most of the time. Questions from lay persons, Members of Congress, for instance, are often very hard to translate into scientific terms because there is no comprehension on the questioner's part of what sorts of things can be answered in a well-defined and quantitative way. To deal with one of those questions, one has to educate the questioner and redefine his question to one that can be answered. I have not, by the way, had any notable success with that process with the Members of Congress.

Asking the right question, that is, getting the scientific and technical objectives of a piece of research correctly defined, is often half the battle. A diffuse or inaccurate definition will almost certainly lead to a diffuse or inaccurate result from the research. Sometimes, it may be necessary to do some research to see what the question should be.

Mr. Chairman, your last question is "How are scientific research results best translated into the regulatory arms of the agency?"

With a large club is the answer I am tempted to give. In my experience, it is not easy to get the regulatory side of the agency to accept and use the research results it so eagerly sought a few years before. Perhaps that is the key to the paradox. The regulators needed some information desperately for an issue that had arisen. They called to the research side, which went to work and had the research carried out. Now the result is in hand, but it is three years later. The regulators had to find some solution to the issue and they didn't have three years. So they mandated some grossly conservative requirement and went on with

their business. From their standpoint, the issue is settled and there is some reluctance to make an active issue of it again by changing the requirements. Of course, if the research indicates something additional is required for safety, then the matter will move. But if it is just to relieve a too-conservative requirement, it does not have much momentum. Besides, the regulators will tell you, they feel very comfortable with the additional margin that conservative interim requirement provides.

A better answer is that the research management section needs to put the research results in a form directly applicable to regulatory staff positions or to agency regulations and rules, and agency management needs to be very firm and insist that the new results be incorporated in current regulatory practice.

Mr. Chairman, before I close these remarks I would like to note an interesting aspect of your question list on science in the regulatory agencies. And that is that your list did not start with the question "Why does a regulatory agency need to do research?" I got pretty tired of trying to answer that question during my time on the Nuclear Regulatory Commission and I understand the oversight and appropriations subcommittees for the agency are still asking it. It is a real pleasure to talk to a committee of the Congress where there is some understanding of the key role that research plays in safety regulation.

Mr. Chairman, I thank you and the Committee on Science and Technology for this apportunity to testify today, and I wish you well in this review of Federal science policy.

Mr. WALGREN. Thank you.

Dr. Goldstein?

Mr. LUJAN. One of the nice things in your written statement was that you never had any trouble with Members of Congress trying to explain what you were up to.

Mr. WALGREN. Dr. Goldstein?

STATEMENT OF DR. BERNARD D. GOLDSTEIN, PROFESSOR AND CHAIRMAN, DEPARTMENT OF ENVIRONMENTAL AND COMMUNITY MEDICINE, UMDNJ-RUTGERS MEDICAL SCHOOL, BUSCH CAMPUS; AND FORMER ASSISTANT ADMINISTRATOR FOR RESEARCH AND DEVELOPMENT, U.S. ENVIRONMENTAL PROTECTION AGENCY

Dr. GOLDSTEIN. Thank you. I, too, appreciate the opportunity to come back here, if you will, more as a philosopher than as a supplicant. It is a much more relaxed approach.

And I do thank the members of the committee for, in a sense, feeling that this is an important enough issue for them to devote their limited time. This is something that speaks very well for the possibility of dealing with these important problems having to do with the control of where is really the best place to do regulatory-related research and how is the best way to do it. Again, as Dr. Hendrie said, I am glad we are past the question of whether it should be done. It clearly should be done.

I am an experimental scientists by training and have in fact returned in part to be able to do some more experimental science. One of the things that one does as an experimental scientist when asked a question is to look and see whether someone has done the experiment already. I think, in a sense, the Federal Government has, in terms of looking at whether or not research should be done in a regulatory agency or should be done in a science based Federal agency.

I think that experiment is, if you will, the comparison or contrast between EPA and OSHA. These are both regulatory agencies required to put out regulations of a variety of types, and I think they are easily comparable in terms of their major overlap which is in the area of health-based regulations for chemical pollutants.

Both of these agencies have had a long and checkered career. Actually, their careers are of about the same length of time. They have both had ups and downs in a variety of ways. I think you can compare them pretty well.

There is a very big difference, though, in terms of where the regulatory science is done. In the case of EPA, the regulatory science is done within EPA. In the case of OSHA, it is done not in the Department of Labor, not within OSHA, but in Health and Human Services as part of CDC under NIOSH. So, it is a separate organizational component.

As well as being an environmental scientist, I am a physician. I am an occupational medicine physician. I run an occupational medicine program. My judgment is, and I think the judgment of just about everybody I have spoken to is that through the years, EPA has done a better job of getting out health-based regulations related to chemicals than has OSHA. I would think that, although we

can point to many factors, a major factor there is the presence of the health scientists within EPA as opposed to being in a separate organization.

And I want to immediately say that I have the utmost respect for the health scientists in NIOSH. I think they are excellent. I think they do a very good job of what they do. I think they have been very underfunded and perhaps can do more, but I think that not being, if you will, cheek by jowl with the regulatory has really hurt OSHA's ability to cut out health based regulations.

It is sort of ironic that one of the areas that NIOSH perhaps can be faulted with is the fact that they have not been able to develop a cadre of top-notch scientists around the country who are really knowledgeable about occupational health. It is a sister agency, it is NIESH, that has been able to do this for EPA.

So, there is a role for, if you will, basic science, more fundamental science, coming out of a nonregulatory agency. There is certainly a role for an organization such as the National Institute of Environment Health Sciences to provide the training grants and incentive programs which will allow the development of scientists—who will then be used in EPA science—who become either EPA scientists, or who become people in universities, or in other programs, who will be funded by EPA to provide the science necessary for the EPA regulatory efforts.

Besides that, there is the need to have research and development done within the regulatory agency. In terms again of the health-based science—and EPA obviously does more—but in terms of comparison with OSHA, it is easiest to compare the health regulations. There is within EPA a critical mass of scientists who are able to do two things.

One is the research and development itself. And the research and development, as Dr. Hendrie has said, that requires the kind of communication so that we can understand the questions that are to be asked. The question is the most important aspect.

At EPA, we have developed a process whereby the original planning is a joint planning between a research and development program and the program offices responsible for air or water or whatever particular program that focuses on what the question should be. It is a truism that scientists do a very poor job of explaining to the lay public what it is that they are doing. It is also a truism that nonscientists have a tough time explaining to the scientist what it is they need to have done.

This exchange is something that I think is really fostered by having your scientists within your regulatory agency. It simply will not occur if your scientists are in a completely different part of the Federal bureaucracy.

It is an exchange that goes on with course-corrections. You can talk about what the science is to regulators who are faced with the problem. They know that they have a year or two to develop the options, go through the various processes.

If, after talking with them, you sort of stay away from them during that period of time, you will find that there will be a gentle straying, not intentional, but a straying nevertheless from what the science base is, from what the technical base is. It is almost as if we started one of those games of whispers, just whisper into one

ear and go around. By the time it gets through a bunch of policy analysts, lawyers, and comes out the other end, it is subtly changed.

You need the continual interaction that occurs not just in the formal meetings that one can have between different agencies, but in the informal meetings, the corridor, picking up the phone, and meeting in the elevator that will keep the options fully based on the regulatory effort. Again, I think this is an argument to keep the research and development program within the regulatory agency to a large extent.

You can't just do it with health advisors or other scientific advisors who come in on a part-time basis or even are there full time if they don't manage any research programs. It is very, very tempting to say, "Why don't we hire a bunch of top-notch scientists and just let them always be at the Administrator's elbow and have them give advice?"

First of all, no one has the kind of breadth that is going to really provide all the advice necessary for an organization such as EPA or OSHA. Most of our regulatory agencies are reasonably broad in their need for different types of science.

Also, science is moving so rapidly that literally breathtaking advances are being made. In terms of health, if you have advisors who are not either performing or managing on-going research, they may be the best in the world right now, but in a few years, they are simply not going to be at the level of the scientists and technical people whom the regulated community have access to. You have to have people in your regulatory agencies who are at least as good as those in the regulated communities or you are going to find that the programs that you develop simply will not get through the courts, will simply not get through the expert review panels, the science advisory board, the National Academy of Sciences, that will be looking at what is done by the regulatory agencies.

I have also answered your questions in another way by listing for you a number of problems that I believe are inherent in a research and development program in a regulatory agency. There is a flip side to this. There are certain problems that simply don't happen in a Federal bureaucracy that is a research bureaucracy that do happen in the R&D program. I certainly had enough of them at EPA.

Most of them are manageable, not manageable in the sense that you are going to cure them, that some stroke of the pen, some congressional act will get rid of them, but manageable because you can recognize them and deal with them. Dr. Hendrie mentioned the different time frames that scientists and regulators act under. But these are manageable, not curable, but can be managed.

For instance, at EPA, I found one of my greatest frustrations would be to sit in with the Administrator or other people making decisions, watching them be very concerned about some major uncertainty in this process that they were working with and knowing that, damn it, if I had only known a year or two ago that this was the uncertainty that would be driving their decision, I couldn't have gotten rid of the uncertainty, but I certainly could have narrowed it down. I could have made it easier to make the appropriate decision had we known sufficiently far in advance.

Well, there are techniques and EPA in the past few years has certainly tried to develop a number of them, which will allow one to get the scientist and the regulator together, the technical person and the regulator together sufficiently early so that one can exchange the information which will anticipate what those decisionmaking processes will be dependent upon.

It is true that those decisionmaking processes at the time that the decision is made one can't say, "Gee, I have a great experiment which, if you give me about 2 years will help you," because Congress and the courts have set timetables that simply are not appropriate to wait that period of time.

Other problems that are inherent in the agency have to do with the lack of flexibility. We have a particularly bad one at EPA having to do with having inadequate resources for our in-house scientists. We are controlled, appropriately so, in the number of scientists that are present there. There are so many full-time equivalent people. There is so much of a budget. There are so many laboratories that must be maintained. I was told when I came to EPA that I could close a laboratory if I wanted to as long as I could find one that wasn't in a congressional district. So, we have very little option dealing with those types of numbers.

What we really have to do then is to be able to use the research and development budget we have for the people we have in-house and for the extramural program. Again, the controls are there to be sure that we don't build new buildings, we don't build palaces, we don't hire extra people, we don't spend money on acid deposition that Congress has decided should be spent on hazardous waste.

But beyond that, at EPA we were given an additional control. We heard earlier about the excellent work at the Jet Propulsion Laboratory. The research and development manager at NASA has the option to be able to use money, budgeted by Congress for certain work, at Jet Propulsion Laboratory or in-house at his own laboratories.

Basically, the kind of restrictions that EPA was under I did not have that type of flexibility. In fact, I had a severe shortage in the availability of funds to do in-house research. We had inefficiencies in-house because of a degree of micromanagement that came out of Congress, out of OMB, out of my own agency, and was based upon the failure to trust the regulatory agency which somehow was taken out upon the Research and Development Program, the scientists, which would not have happened at an agency that was not a regulatory agency.

So, again, unnecessary micromanagement based upon what the regulator has done which has gotten to some degree of displeasure of the various authorities responsible for the budget.

There are other inherent problems in doing the research in the agency. As I say, some of them can be cured. The last one I mentioned is curable, but most of them simply have to be looked at.

I will conclude by thanking you again for the opportunity and by telling you that I really believe, based upon my 2 years of experience, that we can work to get good health-based regulations at regulatory agencies, that we can manage to do a reasonably good job of separating the risk assessment and the risk management func-

tions, and that we can do a good job of controlling the tendencies in regulatory agencies toward misuse of science.

Thank you.

[The prepared statement of Dr. Goldstein follows:]

TESTIMONY

HEARING ON

SCIENCE IN THE MISSION AGENCIES AND FEDERAL LABORATORIES

COMMITTEE ON SCIENCE AND TECHNOLOGY

October 24, 1985

Bernard D. Goldstein, M.D.
Professor and Chairman
Department of Environmental and Community Medicine
UMDNJ-Rutgers Medical School
Busch Campus
Piscataway, NJ 08854

Mr. Chairman, Members of the Committee.

Thank you for inviting me to present my views on science in the regulatory agencies and federal laboratories. As you know, I have just returned to academia from the position of Assistant Administrator for Research and Development at EPA. Your probing questions in the Statement of Purpose for this hearing have led me to list the problems that exist in doing research in a regulatory agency. Before I describe them, and perhaps give the wrong overall impression, let me focus on your first question which asks whether R&D supporting regulatory offices should be under the control of the regulatory agency, or elsewhere in the bureaucracy; presumably a science based organization.

As an academic scientist, I am much more comfortable dealing with experimental evidence rather than with opinions. Fortunately for me, the Federal Government has conducted an experiment which provides information pertinent to the question of where regulatory science and technology should be performed. This is the experiment in which R&D has been included within EPA but excluded from OSHA. OSHA, which is part of the Department of Labor, has its regulatory mission supported by NIOSH, which is associated with the Center for Disease Control and is part of the Department of Health and Human Services. The greatest overlap in the missions of EPA and OSHA is in the area of health based standards for the control of exposure to chemicals. Therefore one can get some insight into which of the two approaches is most effective by comparing the ability of OSHA and EPA to produce health-based regulation of chemicals. Both organizations were begun more than a decade ago, both have experienced periods of strong and weak leadership; ups and downs in funding; and a reasonably similar checkered career in terms of employee morale and other factors pertinent to effective regulation action. In my judgment, and

the judgment of everyone I've spoken to on this matter, EPA clearly has done a better job in producing health-based regulation of chemicals. I give this judgment not only as a scientist who has spent two years at EPA but as a physician in charge of an occupational health program.

I believe that including R&D within the structure of EPA has been an important part of EPA's relative success in this area, although there are many other factors that have played a role. Let me immediately state that I am not arguing that EPA has better health scientists who have done more effective research than NIOSH supported scientists. I have the upmost respect for the capabilities of NIOSH, although it has been grossly underfunded. NIOSH can be faulted for not having done a fraction of what needs to be done to ensure that there are highly qualified occupational health scientists in the nation's academic programs providing the R&D necessary for NIOSH activities. It is somewhat ironic that it has been a sister NHS organization, NIEHS, that has been responsible through the judicious use of training programs and center grants for a major part of the availability of top notch scientists to work in or with EPA, and provide it with the scientific base leading to effective regulation.

The presence of an R&D program within EPA has led to a critical mass of health scientists who participate not only in the development of pertinent scientific data but, most importantly, in the translation of the world's literature into the basis for regulatory decision-making. Of significance is that at EPA this is done by a separate line organization headed by an Assistant Administrator, a political appointee. This helps maintain organizational recognition of a legitimate role for R&D as part of the Agency's mission, and provides the opportunity for the individual responsible for health science to give the information on which regulation is based to the highest levels of the Agency. This exchange of information, and the

important course corrections that are needed as non-scientists stray from the acceptable data base, occurs not only through formal meetings and position papers, but to a large extent through multiple informal exchanges in offices, elevators, corridors and the other interactions that characterize any effective organization. Note that this is a 2-way exchange. It is a truism that scientists do a poor job in translating what they know to the non-scientist. I can attest it is also a truism that non-scientists have great difficulty in describing to scientists what it is they need to know to be able to make a regulatory decision. At EPA we set up a formal process for research planning in which the questions to be asked were determined jointly by the Office of Research and Development and the appropriate program office. Of importance, ORD's success in obtaining support within the Agency is dependent on the success of this interaction, in essence on the ability to provide information which is necessary for regulation. Such a close and effective association can not be obtained when the health science activity is performed in a separate federal bureaucracy. Nor can this be accomplished simply by having well-qualified health scientists serve in advisory roles. First of all, the communication required is not just at the senior levels of the agency, but throughout. In fact, in terms of timely regulation, it is crucial that junior and mid-level policy analysts and lawyers have the benefit of communication with health scientists: failing this an otherwise well worked out regulatory package will be turned down on scientific grounds at a high agency level only after many months of work at lower levels, or a research approach that could have provided information needed to narrow uncertainty will be recoganized much too late in the regulatory process to be of timely value. Another problem with an approach primarily depending upon using scientific advisors is that it fails to recognize the essential feature

of modern health science - its rapid progress. Breathtaking advances are being made every day. Health advisors who are not performing or managing active research programs simply can not be expected to provide information over the long term that will successfully pass review by a a Science Advisory Board, or stand up in court. Regulatory agencies must have scientists who are at least as qualified as those available to the regulated community.

Let me now turn to the problems of R&D in a regulatory agency, and in this discussion I refer to all of R&D and not just to the health studies used as an example for the comparison of OSHA and EPA. The problems are many. The one of greatest concern is the possibility that risk assessment and risk management will not be kept separate, that the scientist will only provide those answers convenient to the regulator. I will not tell you that has not happened at EPA in the past, nor that it can not happen in the future. However, the current approach which relies heavily on external peer review through the Science Advisory Board and other mechanisms should make recurrences much less likely. The scientific community has a vested interest in seeing that EPA's risk managers are restricted to participating in determining the questions to be asked, not the answers that are given.

There are other problems that are specific to performing research in a regulatory agency. A major one is the frequency in which well-planned pertinent ongoing research must suddenly be stopped. This is highly inefficient, more so than the stops and starts so frequent in the regulatory world, in that the restarting process is exceptionally costly for the type of research that is done by EPA. Suddenly stopping an EPA reseach project often wipes out the whole investment. Sometimes this is justified. As public servants it is appropriate for EPA scientists to respond to sudden public needs, often expressed through Congress, such as Love Canal, dioxin, etc. In fact, it is the need to respond quickly which is a partial justification for

having scientists directly responsive to an Administrator who can make the judgment that the provision of information on a new topic justifies the sacrifice of an existing programmatic need. This is difficult to do if the scientists who will be impacted by the change work in a completely different part of the bueaucracy. The wise R&D manager has bufffering systems in place to allow some flexiblity in switching R&D objectives. However, in my experience, only rarely is the need to stop ongoing research, with its associated waste of taxpayers' money and adverse impact on scientists' morale, justified by new work to be done. The major cause of this problem, at least at EPA, is a budgeting process that simply is not congruent with the realities of the efficient performance of R&D. Unfortunately, I believe there is a tendency for this to be inherent in a regulatory agency, although much improvement can be made. There are two major causes, one within the agency and a second in which Congress and OMB can be added to the list of culprits. Within the agency there is what I call the "green eyeshade syndrome". A well-documented positive aspect of modern bureaucracies is the frequency with which technocrats, such as accountants, become firmly imbued with the mission of the agency. In a federal research bureaucracy the mission is research; at a regulatory agency it is regulation. It is no wonder that EPA's budgetary staff has treated the agency's R&D budget as a piggybank often producing highly negative and wasteful long term effects on the R&D needed to support regulatory decision-making in exchange for transitory immediate gains for a floundering regulatory program. The second budgetary problem leading to inefficiency and morale problems that tends to be particular to a regulatory R&D program is the unwarranted degree of control exercised by individuals in EPA, at OMB and in Congress who simply do not understand the first thing about managing an R&D program. Note that I am not objecting to control in principal

by all levels, it is the degree of control. Certainly it would be wasteful to ask EPA accountants, or Congress or OMB to choose the strain of rat for an experiment. While it has not gone that far it is in that direction that controls have hamstrung EPA's R&D efforts. One important example is the restrictions placed on EPA's in-house research program which greatly jeopardizes the productivity of 1800 dedicated federal employees. Unique among all federal R&D organization, including other regulatory agencies, EPA is restricted in using its research budget for in-house projects. This would not be as major a problem if the approach to the budget by Congress and the executive were appropriate. In fact, actions by Congress and OMB tend to make a mockery of the very careful R&D planning undertaken within the agency. Last minute changes in total budgets and particularly in subdivisions of the budget, are made for reasons extraneous to the research planning. That of course happens to some extent at every federal agency, but at EPA it is uniquely difficult to manage because of the additional micromanagement by individuals incompetent to manage an R&D program. The net result has been to greatly impede the ability of EPA's in-house R&D program to effectively perform research planned and budgeted completely in agreement with the dictates of the Administration and of Congress. Please note that I am not talking about more money, nor am I talking about relaxing controls on the number of employees or the use of funds to build or renovate laboratories; what I am attempting to describe is a situation in which the manager of R&D at EPA has lost the flexibility to decide whether planned research should be performed at EPA laboratories or extramural laboratories, and is forced into making unreasonable and counterproductive demands on EPA laboratory scientists. This problem began in the Carter Administration and accelerated in the Reagan Administration. It is unique to a regulatory agency in that it reflects actions taken because of a dissatisfaction and distrust with the

regulator. It can and should be reversed.

There are other problems in doing research in a regulatory agency that are not reversible in the sense that there is no law of Congress or management approach that will provide a final solution. Rather, these are problems inherent to regulatory agency research.

An example of an inherent problem is the difficulty in obtaining validation of models and other tests used in regulatory efforts. EPA is justly proud of its ability to produce models for the calculation of exposure, or batteries of tests to predict chemical toxicity. However, as has recently been pointed out by the Science Advisory Board, EPA should be doing a better job of validating, or field testing, to test the accuracy of predictive models or tests. The reason for this is related to the interface between regulation and research. Scientists are relatively conserative in the use of data. If left to ourselves, we might go to 18 decimal places before we will accept a fact. On the other hand, regulators do not have the time to wait for 18 decimal places. This leads within the agency to budgeting decisions each year which favor developing a new model or test battery for another problem rather than validating the existing one. A somewhat related inherent problem of doing research in a regulatory agency is the different time frames of scientists and regulators. The time frame of the regulatory process, very ofren conditioned by Congress, puts pressure on scientists to do or accept less than optimal R&D in order to satisfy a short-term need. An R&D manager must be alert to insure that the quality threshold is always exceeded. This can be done by careful attention to quality assurance and quality control (QA/QC). But again, it is difficult to convince regulators of the need for QA/QC due to their greater willingness to accept any number they can get.

Other problems inherent in doing R&D in a regulatory agency relate to the

planning process. In deciding which investigators to support, scientists tend to focus on past track records while regulators look more at what is said will be done, as in an essay contest. The uncertainties of research outcome tend to hamper wise investment in relatively high risk research which might be extremely beneficial to the regulatory mission, but whose outcome is not fully predictable...

Having listed some of the problems inherent in doing research in a regulatory agency, let me immediately emphasize that all of these problems are manageable. By manageable I don't mean in the sense of a final cure. However, if one recognizes these problems, and works at them, they can be ameliorated.

A question frequently asked is whether EPA's research effort unnecessarily duplicates that supported by other federal agencies. The answer is no. Let me discuss health research since this represents the greatest likelihood for overlap, given the strength of federally supported environmental health research. My judgment in this area is based in part on my past experience as Chairman of the NIH Toxicology Study Section, which reviews and assigns priority for the funding of research grants in Toxicology, and also as the recipient of three NIH grants. The distinction between EPA supported and NIH supported health science research is subtle, but it is real and of great importance to providing the type of research findings necessary for effective regulation. In essence, NIH supported research provides the basic science on which regulatory health science is based. A high quality proposal aimed at establishing the underlying mechanism by which a pollutant produces an adverse effect will be funded by NIH; a proposal of a similar quality aimed at utilizing this mechanistic insight to establish the lowest observed effect level or other numerical risk data of value to the regulator would almost certainly not receive sufficient priority from an NIH Study

Section to be funded. Let me emphasize that the regulator could not ask questions related to risk if the mechanistic insight had not first been provided by NIH funded research. Accordingly, both are needed: the free-floating high risk basic science approach in which the role of the government is to assign priorities over relatively broad areas and to ensure that there are sufficient experts trained in our universities and sufficient tools for these experts to provide the basic foundation without which advances will not occur, and the more directed research aimed at answering specific questions of importance to the regulator in which close interaction between regulators and scientists is a necessity so as to define the question in a form that will provide an answer. Central to all research is the need to define the problem in terms of crucial experiment. To the academic scientist a crucial experiment is one that tells us something we didn't know before, or to be trite, one that advances the frontiers of science. To the regulatory scientist the definition of crucial is related to the mission of the agency, but otherwise the same need is there. Note that this is not equivalent to a distinction between long-term and short-term, or basic and applied. Certain long-term basic questions can be identified as crucial to the needs of a regulatory mission and should be funded (e.g. better understanding of the mechanism by which different soils interact with groundwater contaminants).

Let me also point out that one must distinguish between overlap in the managing of R&D, which produces wasteful duplication and confused signals, and overlap in the performance of R&D, which is the normal way that science and technology progress. Contrary to the public image, isolated scientific and technical breakthroughs are exceptionally rare. Advances in knowledge require replication, preferably by different scientists using varying approaches, before they will be accepted. A good R&D manager acts to allow some

redundancy in research efforts, particularly on the margin between scientific areas. This is more preferable to rigid lines of demarcation which allow needed research to fall in the gap.

Your question concerning whether research of value to the mission of a regulatory agency is best done in the regulatory agency, or in a separate scientific organization, is particularly timely. There is now under consideration the funding of research and development under the Superfund bill, something that is desperately needed, and the appropriate venue for such funding. There appears to be a sentiment in Congress toward giving major control of the R&D funding to the Agency for Toxic Substances and Disease Registry (ATSDR). This would be a mistake for at least four reasons. First of all, it flies in the face of the "experimental" results which show EPA having a better track record than OSHA in using health science. In this regard, it should be noted that ATSDR occupies approximately the same position as NIOSH in the HHS table of organization. Secondly, for most of the R&D areas needed for Superfund decision making, ATSDR does not have the scientific or technical strength. Given the immediate needs of Superfund, it appears inappropriate to build new areas into ATSDR which duplicate existing strengths at NIEHS, EPA and the nation's universities. As part of CDC, ATSDR does have major important strengths in epidemiology and should be strongly supported to perform the necessary hands-on disease registry studies at Superfund sites, and related research.

Thirdly, for this important program requiring rapid response, the power to demand this flexibility is removed from the head of EPA who bears the responsibility for decisions made on the basis of the R&D products. Accountability without authority is a prescription for failure. Fourthly, there is a very strong potential for managerial overlap leading to confusion. In the not unlikely event that ATSDR will provide a somewhat different

interpretation of the risk of a toxic substance than does EPA's R&D program, to whom does the Administrator of EPA listen? There is little sense in building ATSDR up to have expertise in a broad area, particularly risk assessment, unless Congress intends for the Administrator of EPA to use its advice. But, by the same token, the advice given by EPA's R&D program, which has a leadership role in risk assessment and which relies heavily on outside scientific peer review, will presumably still be relied upon for the other dozen or so Acts which are under the responsibility of the EPA Administrator. To have the head of EPA use one inherent risk number or finding for a compound when it is regulated under Superfund, and another number when it is regulated under the Clean Air Act, is a prescription for administrative paralysis which, at a minimum, will further slow up a process that Congress has frequently criticized for its slowness.

In summary, I would answer your question by saying that it does matter where in the bureauracy regulation-related research lies. Mission oriented agencies can best accomplish their mission if they maintain R&D programs. As I have discussed, there are certain problems that are inherent in performing R&D in a regulatory agency. But these can be dealt with, and such problems are far outweighed by the benefits of performing R&D in a situation where one optimizes the ability to ask the right questions, and where the scientist and engineer can be most responsive to the needs of the mission.

Mr. WALGREN. Thank you, Dr. Goldstein.
Mr. Jorling?

STATEMENT OF THOMAS C. JORLING, PROFESSOR OF ENVIRONMENTAL STUDIES, WILLIAMS COLLEGE, WILLIAMS TOWN, MA; AND FORMER ASSISTANT ADMINISTRATOR FOR WATER AND HAZARDOUS MATERIALS, U.S. ENVIRONMENTAL PROTECTION AGENCY

Mr. JORLING. Thank you, Mr. Chairman. I, too, am pleased to be here and honored to speak to these issues. I do commend you and the staff for the work that you have performed, not just with the issue that we are speaking to but the overall question of science policy in the Federal Government.

Unlike my two colleagues, I come to this task as one who speaks as an environmental regulator and not as an environmental scientist. I spent time leading a regulatory arm of EPA, not the research arm. I, too, will direct my responses to the questions you specifically raised in your letter of invitation.

On the first question, I share the affirmative answer that both of the preceding witnesses have given. I would add some emphasis to it. I would say that not only is the answer yes that a regulatory agency must have an in-house R&D program, but that it is decisively and emphatically yes.

The regulatory agencies should maintain R&D programs within their organizations. The R&D necessary to support regulation should not, and I would add even stronger, cannot be conducted in another agency or agencies. It does make a difference where and by whom regulation related research is performed.

EPA is an example of a regulatory agency charged by Congress in a series of major enactments with a most important but difficult task, simply put, to protect public health and to enhance and maintain the integrity and quality of the environment. It is a difficult task because it involves all of the following: science and technology; economic factors; health and welfare; volatile political dynamics, uncertainty, and emotion. And lest anyone misinterpret the inclusion of this latter point, I strongly value the emotional element in these processes.

Above all, environmental regulation involves large numbers of very diverse people and institutions, all having very different views and interests on any typical environmental issue. It involves the States and, often, local government. It involves public and private officials. It impacts nearly every sector of our society. Thus, environmental regulation is and it must be a competitive process. It is a competitive political process, competitive in the sense that all parties work very hard, and some employ huge banks of resources, to represent their interests at every step of the process.

In the context of science, what comes before the agency is advocacy science. No one should be under any illusion that the science that is injected into rulemaking and decisionmaking is calm, dispassionate, objective, neutral, and rational. It is not. Science, or the mantle of science, is advanced to make a point. Not once in my experience has a representative of the regulated sector come forward and said, "Our scientific research reveals we have a problem on

which we need tighter regulation." Establishing that fact is a burden on Government, on the public, or on the environment. It is in this sense that science introduced into the regulatory process is advocacy science.

I believe this competitive process is important to the success of democracy. It involves wide participation; although great disparities in access to resources can distort that participation, especially in the area of science and technical issues. It avoids tyranny of the "expert". It avoids making big errors. It might be slow and it might be messy, but it represents better government than any alternative that has been proposed.

Essential to the ability of EPA to serve in a decisionmaking capacity in such processes is the availability of a competent scientific research and technical arm. Simply put, EPA—and I believe any agency regulating in the area of health and the environment—must have scientific and technical resources that are operating not only under the same mandate from Congress but also within the same organization that is responsible for the ultimate regulatory performance. Just as the regulating arms of the executive branch need congressional authorization and direction and also need to be accountable to Congress and the courts, so too does the scientific and technical arm. Science in these areas needs to be responsive to public policy; responsive in what it pursues, when it pursues it, and how it pursues it. In short, it is necessary to support the regulatory process.

To the objection that science can't be directed or accelerated or operated in any hurried or hassled environment, I say nonsense. Often, such an objection, made in the tone of utmost reasonableness, is, simply put, B'rer Rabbit asking not to be thrown in the briar patch. Any knowledgeable observer or participant knows a very effective way to hobble a regulatory agency is to remove its control over the scientific and technical personnel or otherwise reduce its capacity to perform such work. That is, seeking to deprive EPA of its scientific resources is a tactic in an effort to seek a desired outcome, usually, an outcome in the form of delayed or avoided regulation.

In areas of public policy, science can be directed, even hurried. The Manhattan project and the man on the Moon are loud testaments to that fact. In the context of EPA regulation—and I share Dr. Goldstein's views on this—scientific and technical work has supported work having the effect of protecting health and environment long before actions would have been taken if EPA was dependent upon so-called neutral, if not neutered, source of science and technical assistance.

I am speaking here to the issue of whether EPA should have a research arm, not to issues which relate to the question of whether EPA science can't be made better or more integrated into decisionmaking. Your first question is of a much larger scope than leadership and management in the agency. If we have time, I will address those later.

Let me recite real world experience in support of a regulatory agency having its own scientific and technical resources. The results of EPA decisionmaking, generally rules, are nearly always subject to judicial review. The courts are asked, in effect, to judge

the defensibility of actions taken by the agency. Often, those rules have a strong scientific and technical component or basis, and that component or basis is nearly always attacked by the challenging parties.

EPA has several sources for its scientific and technical needs. Sometimes, because of the exigency of a situation, it must depend on whichever of these sources is available. Sources of scientific information include the regulated community itself, the States, the literature, grantees, consultants, and contractors, and, of course, EPA's own staff.

It is appropriate to ask, then, which source of science and technical support is the most dependable, dependable in the sense that it withstands the scrutiny of the courtroom. That answer, according to every attorney I have interacted with at EPA and in the Department of Justice and in every case that I am familiar with, is EPA's own scientific and technical staff. In fact, repeatedly, as part of rulemaking activities, I have had EPA lawyers advise me repeatedly that regulations were not defensible unless they were supported by EPA work.

Remember what is involved here. For one, a willingness to stand behind, in public, often on the witness stand, the science and the judgments and conclusions drawn from it. Suffice it to say that neutral scientists do not like to be cross examined.

Second, science in the regulatory process involves an exact level of quality control. People who are not on the anvil of the legal process are notoriously sloppy. The standards of quality control demanded of science and technical questions in public policy are much greater than in the scientific methods otherwise operating in academia. It is more demanding because real consequences, often investment of substantial resources, flow from the actions of EPA. Only persons in such an institution and held accountable to such standards are typically ready to withstand that kind of scrutiny.

So-called independent consultants or contractors, and here I am sorry to say I would for the most part include the National Academy of Sciences, are never independent of the sources and potential sources of funds or of the bias of the personnel who comprise such organizations. Repeatedly, in my experience, EPA contracts for scientific and technical support were made with firms or organizations that also perform similar services for the regulated sector. Such contractors are not and cannot be unmindful of the effect of their results under such contracts on present or future clients.

Enough said except for one related point, and this again bears on one of Dr. Goldstein's points. It is important to ask why EPA depends on contractors at all. The most important reason is a budget principle, a budget principle common to all administrations, that makes it easier for an agency to get contract money than to obtain authorization internal or civil service personnel. The principle is supported by an assumption that I believe to be fundamentally flawed, that it is cheaper in the long run to hire a consultant, even at a much higher rate of cost and with lower performance, than a civil servant. The existence of the "Beltway Bandits" is testimony to the beneficiaries of this budget assumption. The beneficiary of this principle certainly isn't the public interest or the taxpayer.

Your second question deals with maintaining quality science in the face of regulatory deadlines.

In general, there is no obvious structural solution to the problem implicit in this question. Assuring quality, and I would add relevant science, in the rulemaking process depends a great deal on leadership and management, in short, on good people. As a result of my experience, I can suggest several themes that bear on these questions but I recognize fully that in the end they may be no more than mere exhortations.

The regulators, budgeters, and planners in the agency must respect the needs, the personnel needs, the equipment needs, the budget need, and the procedural needs of R&D. This means sufficient resources must be assured for R&D. The first cuts in times of austerity, a perpetual condition now, can't simply be taken from R&D. The level of commitment must be sustained over the long haul. Simply put, the pattern of the last 5 years or so which resulted in a 50-percent reduction in EPA R&D resources at the same time the agency was faced with major new responsibilities cannot be allowed to be repeated.

Second, R&D personnel, especially R&D leaders, must interact with regulatory personnel. Regulations and public policy decisions are much more effective if both the regulator and the R&D arms are marching to the same drummer—a drummer which, in the final analysis is Congress sounding through its statutory authorizations and in its oversight responsibility.

I am a firm believer in deadlines, a believer even long before they were demonstrated to work. Normally, in health and environmental protection, there is never a time when the science is complete. Consequently, it becomes a question of judgment, scientific and regulatory judgment, when there is enough information to act and, with good leadership, R&D can supply that amount of science and technical information plus assist in making appropriate judgments about it on a timely basis. I think it is a strawman, if not a diversion, to point to incomplete science as an attack on regulatory deadlines. Science is never complete. The issue is when and whether prudent judgments, informed by science, can be made.

I have combined your last two questions for the purposes of my final comments. I do so because I think, in effect, they represent the front and the back end of the same issue, specifically, the issue of how regulatory and scientific personnel communicate. This is another issue for which structural solutions are secondary to good people, and I can again only make suggestions. R&D personnel should be involved on the work groups, task forces, or whatever is called the committee responsible for moving the regulation or public policy decision forward. I think, at least in form, this is standard practice, but to make it work, the R&D personnel must have access to resources so that as questions arise with scientific and technical dimension, those questions can be addressed on a timely basis.

I am concerned that the text of these two questions suggests a degree of disjunction between science and regulation which I do not believe exists. The science/nonscience division is not a clear one in public policy issues involving health and the environment. There are no discrete parts of any issue which can be split off into the

domain of science and treated differently and then simply plugged into decision formulas. All elements of a complicated policy issue need good science, good analysis, good process, and ultimately reasoned judgment. This can only be accomplished by teams working together with the people responsible for the different elements of an issue, the science, the economic analysis, the policy analysis, all contributing their respective knowledge in the overall process of developing a regulation or making a decision. What the scientist needs to participate effectively in such process is stable, adequate resources and staff in laboratories or in the field and the lead time to perform the work.

My point is that neither science nor the scientist is or can be immune from the give and take of the rulemaking or public decisionmaking process. The scientific issues are woven too deeply into policy issues.

I would like to summarize to this point. I believe it is absolutely essential for agencies such as EPA that regulate in difficult and complicated technical areas to have R&D capacity. That capacity should be meaningful, that is, properly staffed, equipped, and funded. Moreover, scientific and technical personnel must be integrated into every stage of the rulemaking or decisionmaking process. Only in such a manner can the scientific and technical component of issues be incorporated soundly into public policy. These are highly competitive processes, and the agency must have skilled professionals, scientists and nonscientists alike, operating together to carry out the mandate of Congress.

This is not to say that everything is fine in EPA relative to science. It isn't. But on the macroscale question, I am saying that EPA must have a research arm, and it must be given adequate staff, equipment, and funds. It must also be fully involved in the decisionmaking process of the agency.

These elements are essential. Given them, the agency can perform, perhaps not always well, but perform through periods of upheaval or turmoil at the top such as we have recently witnessed, and through periods when events and issues emerge which dominate the political and public perception.

Thank you, Mr. Chairman. I would be happy to answer any questions.

[The prepared statement of Mr. Jorling follows:]

TESTIMONY

THOMAS C. JORLING
WILLIAMS COLLEGE, WILLIAMSTOWN, MA.
BEFORE THE TASK FORCE ON SCIENCE POLICY
OF THE U.S. HOUSE OF REPRESENTATIVES COMMITTEE
ON SCIENCE AND TECHNOLOGY

Mr. Chairman and Members of the Task Force, I am honored by your invitation to appear before you on issues of Science and the Mission Agencies and Federal Laboratories. My comments to you are informed by three principal experiences. First service on the staff of the U.S. Senate Committee on Environment and Public Works during the period 1968-72; a period which included the birth of EPA and the enactment of several of its principal authorizing statutes. Second, service as Assistant Administrator of EPA for Water and Hazardous Materials during the period 1977-79; with responsibilities for implementing four major regulatory statutes; the clean Water Act, the Ocean Dumping Act, the Safe Drinking Water Act and the Resource Conservation and Recovery Act and third, service as a student and teacher of environmental protection as a Professor of Environmental Studies at Williams College from 1973-77 and from 1980 to the present. In the context of this hearing, my remarks will focus on the role of science in environmental regulation, primarily as that regulation is carried out by the U.S.E.P.A. My views are those of an environmental regulator, not those of a scientist. They are the views of one who has lead a regulating arm of EPA, not a research arm.

You and your staff are to be commended for the preparatory work on these hearings and the overall study of Science Policy. I am going to take the specific questions in your letter of invitation as a starting point for my comments.

Question 1.

> "Should regulatory agencies maintain R&D programs, or should their be conducted by another agency or agencies? In other words, does it matter where in the bureaucracy regulation-related research lies?"

The answer is most decisively and emphatically yes. The regulatory agencies should maintain R&D programs within their organizations. The R&D necessary to

support regulation should not, even stronger, cannot be - conducted in another agency or agencies. It does make a differnece where and by whom regulation-related research is performed.

EPA is an example of a regulatory agency, charged by Congress in a series of major enactments with most important, but difficult tasks: simply put, to protect public health and to enhance and maintain the integrity and quality of the environment. It is a difficult task because it involves all of the following: science and technology; economic factors; health and welfare; volatile political dynamics, uncertainty, and emotion. And lest anyone misinterpret the inclusior of this latter point - I strongly value the emotional element in these processes.

Above all, environmental regulation involves large numbers of very diverse people and institutions; all having very different views and interests on any typical environmental issue. It involves the states and often local government; it involves public and private officials. It impacts nearly every sector of our society. Environmental regulation is a competitive process, competitive in the sense that all parties work very hared, and some deploy hugh banks of resources, to represent their interests at every step in the process.

In the context of science - what comes before the Agency is advocacy science. No one should be under any illusion that the science that is injected into rulemaking and decisionmaking is calm, dispassionate, objective, neutral and rational. It is not; science or the mantle of science is advanced to make a point. Not once in my experience has a representative of the regulated sector come forward and said our science research reveals we have a problem on which we need tighter regulation. Establishing that fact is a burden on government, or the public, or the environment. It is in this sense that science introduced into the regulatory processes advocacy science.

I believe this competitive process is important to the success of a

Democracy. It involves wide participation; although great disparities in access to resources can distort that participation, especially in the area of science and technical issues. It avoids tyranny of the "expert". It avoids making big errors. It might be slow, it might be messy, but it represents better government than any alternative that has been proposed.

Essential to the ability of EPA to serve in a decision making capacity in such processes is the availability of a competent scientific research and technical arm.

Simply put EPA - and I believe any agency regulating in the area of health and the environment - must have scientific and technical resources that are operating not only under the same mandate from Congress, but also within the same organization that is responsible for performance. Just as the regulating arms of the Executive Branch need Congressional authorization and direction, and also need to be accountable to Congress and the Courts, so to does the scientific and technical arm. Science in these areas needs to be responsive to public policy; responsive in what it pursues, when it pursues it, and how it pursues it. In short, it is necessary to support the regulatory process.

To the objection that science can't be directed or accelerated or operate in any hurried or hasseled environment, I say nonsense. Often such an objection - made in the tone of utmost reasonableness - is, simply put, B'rer Rabbit pleading not be to thrown in the Briar Patch. Any knowledgeable observer or participant knows a very effective way to hobble a regulatory agency is to remove its control over it scientific and technical personnel. That is seeking to deprive EPA of its scientific resources is a tactic in an effort to seek a desired outcome - usually an outcome in the form of delayed or avoided regulation. In areas of public policy, science can be directed, even hurried. The Manhattan Project and the Man on the Moon are loud testament to that fact. In the context of EPA regulation, science

and technical work has supported action having the effect of protecting health or the environment long before actions would have been taken if EPA was dependent on a so called independent neutral, if not neuter, source of science and technical assistance.

I am speaking here to the issue of whether EPA should have a research arm - not to issues related to making EPA's science better or more integrated into decision making. Your first question is of a much larger scope than leadership and mangement in the Agency. If we have time I will address those issues later.

Let me recite real world experience in support of a regulatory agency having its own scientific and technical resources. The results of EPA decision making - genrally rules - are nearly always subject to judicial review. The courts are asked in effect to judge the defensibility of actions taken by the agency. Often those rules have a strong scientific or technical component or basis and that component or basis is nearly always attacked by the challenging parties.

EPA has several sources for its scientific and technical needs. Sometimes because of the exigency of a situation, it must depend on whichever of these sources is available. Sources of scientific information include the regulated community, the States, "the literature," consultants and contractors, and, of course, EPA's own staff. It is appropriate to ask - which source of science and technical support is the most dependable; most dependable in the sense that it withstands the scrutiny of the courtroom. The answer according to every attorney I interacted with at EPA and the Department of Justice was EPA's own scientific and technical staff. In fact, I had EPA lawyers advise me repeatedly that regulations weren't defensible unless they were supported by EPA work. Remember what is involved here. For one, willingness to stand behind - in public, often on the witness stand - the science and the judgements and conclusions drawn from it. Suffice it to say, "neutral"

scientists do not like to be cross-examined. Second, science in the regulatory process involves an exact level of quality control; people who are not on the anvil of the legal process are notoriously sloppy. The standards of quality control demanded of science and technical questions in public policy are much greater than in the scientific methods otherwise operating in academia. It is more demanding because real consequences, often the investment of substantial resources, flow from the actions of EPA. Only persons in such an institution are typically ready to withstand that kind of scrutiny. So called independent consultants or contractors - and here I am sorry to say I would for the most part include the National Academy of Sciences - are never independent of sources or potential sources of funds or of the bias of the personnel who comprise such organizations. Repeatedly in my expereince EPA's contracts for scientific or technical support were made with firms or organizations that also performed 'similar' services for the regulated sector. Such contractors are not - and cannot be - unmindful of the effect of their results under such contracts on present or future clients. Enough said, except for one related point.

It is important to ask why EPA depends on contractors at all. The most important reason is a budget principle - common to all administrations - that make it easier for an agency to get contract money than to obtain authorization to hire civil servants. The principle is supported by an assumption, that I believe to be fundamentally flawed, that its chepaer in the long run to hire a consultant - even at a much higher rate of costs and with lower performance - than a civil servant. The existence of Beltway Bandits is testimony to the beneficiaries of this budget assumption. The beneficiary of this principle certainly isn't the public interest or the taxpayer.

Question 2.

> "How should regulatory agencies maintain quality science in the face of regularoy deadlines?"

In general there is no obvious structural solution to the problem implicit

in this question. Assuring quality, and I would add, relevant science in the rule-making process depends a great deal on leadership and management - in short on good people. As a result of my experience I can suggest several themes that bear on these questions, but I recognize fully that, in the end, they may be no more than exhortations.

The regulators, budgeters, and planners in the agency must respect the needs; personnel needs, equipment needs, budget needs and procedural needs of R&D. This means sufficient resources must be assured for R&D. The first cuts in times of austerity - a perpetual condition now - can't be simply taken from R&D. The level of commitment must be sustained over the long haul.

Second. R&D personnel, especially R&&D leaders, must interact with regulatory personnel. Regulations and public policy decisions are much more effective if both the regulator and the R&D arms are marching to the same drummer, a drummer which in the final analysis is Congress, sounding through its statutory authorizations and in its oversight responsibility.

I am a firm believer in deadlines - a believer even before they were demonstrated to work. Normally, in health and environmental protection there is never a time when the science is "complete." Consequently, it becomes a question of judgement, scientific and regulatory judement, when there is enough information to act and, with good leadership R&D can supply that amount of science and technical information, plus assist in making appropriate judgements about it on a timely basis. I think it is a straw man, if not a diversion, to point to "incomplete science" as an attack on regulatory deadlines. Science is never complete. The issue is when and whether prudent judgements informed by science can be made.

Question 3.

> "How should a regulatory agency translate regulatory questions framed by non-scientists into scientific questions that research can address?"

Question 4.

> "How are scientific research results best translated into the

regulatory arms of the agency?"

I have combined these two questions because, in effect, they represent the front and backend of the same issue: how do regulatory and scientific and technical personnel communicate. This is another issue for which structural solutions are secondary to good people and again I can only make suggestions. R&D personnel should be involved on the work groups, Task Forces, or whatever is called the Committee responsible for moving a regulation or public policy decision forward. I think, at least in form, this is standard practice, but to make it work, the R&D personnel must have access to resources so that as questions arise with a scientific or technical dimension, those questions can be addressed on a timely basis.

I am concerned that the text of these two questions suggests a degree of disjunction between science and regulation which I do not believe exists. The science - non-science division is not a clear one in public policy issues involving health and the environment. There are no discrete parts of any issue which can split off into the domain of science and treated differently and then simply plugged into decision formulas. All elements of a complicated policy issue need good science, good analysis, good process and ultimately reasoned judgement. This can only be accomplished by teams working together with the people responsible for the different elements of an issue - the science, the economic analysis, the policy analysis - all contributing their respective knowledge in the overall process of developing a regulation or making a decision. What the scientist needs to participate effectively in such process is stable, adequate resources and staff in laboratories or in the field, and the lead time to perform the work.

My point is that neither science nor the scientist is, nor can be immune from the give and take of the rule-making or public decision making process. The scientific issues are woven too deeply into the policy issues.

I would like to summarize to this point. I believe it is absolutely essential for agencies such as EPA that regulate in difficult and complicated technical areas to have R&D capacity. That capacity should be meaningful; that is properly staffed, equipped and funded. Moreover, scientific and technical personnel must be integrated into every stage of the rule making or decision making process. Only in such manner can the scientific and technical component of issues be incorporated soundly into public policy. These are highly competitive processes and the Agency must have skilled professionals, scientist and non-scientist alike, operating together to carry out the mandate of Congress.

This is not to say everything is fine in EPA relative to science. It isn't. But on the macro-scale question, I am saying EPA must have a research arm, and it must be given adequate staff, equipment and funds. It must also be fully involved in the decision making processes of the Agency. These elements are essential; given them the Agency can perform - perhaps not always well - but perform through periods of upheaval or turmoil at the top, such as we have recently witnessed; and through periods when events or issues emerge which dominate the political and public perceptions.

Mr. WALGREN. Thank you, Mr. Jorling.

I hear Dr. Hendrie saying that there has to be a pretty complete separation, and then I hear both of the succeeding gentlemen saying there has to be pretty close contact. Can these views be reconciled? Have you, Dr. Hendrie, been sitting there saying, "Gee, I disagree with what these folks are saying"? Or did you folks, in listening to Dr. Hendrie, say you were in disagreement with him?

Dr. HENDRIE. In establishing research projects, you can certainly and must establish projected schedules. Research people, like other people, can attempt to make schedules.

My own view is that the difference you sense here on the panel derives in good part from the differences in the way in which our mother agencies conduct their affairs. EPA has always had in-house laboratories. I come from the Atomic Energy Commission, Department of Energy, Nuclear Regulatory Commission side of the Government where we have never had in-house laboratories and have always felt much the stronger technically for that position.

The fact that my colleagues on the panel talk about pushing the researchers to get it out, I think, makes my point. If you want the science pushed around to satisfy tomorrow's deadline of the regulators, that is what you will get with an in-house laboratory because those pressures will inevitably go right down the line as my colleagues have suggested they do. My view is that isn't helpful to good science.

It gets you a partial answer but leaves you in poor shape for the long term. When we want that kind of quick answer in the atomic energy business, we call up half a dozen or a dozen people who are as good as any in the world on that subject and get them together and they make their best estimates out of the depth of their experience and knowledge, and that is the basis on which you have to go with this afternoon's regulatory solution.

But if you want to do science and you want to really know what the answers are, the work will come along at the pace that capable people are able to push it and not one day sooner because there is some guy up here saying I have to have it.

Mr. WALGREN. Gentlemen, would you like to respond?

Dr. GOLDSTEIN. I think, actually, I am in reasonably close agreement with Dr. Hendrie on a lot of the points he has made. He is absolutely right that there is an inherent problem within a regulatory agency that will lead to a tendency to sacrifice long-term needs for short-term gains. But there is another side to that which I think is very positive, and that is that many of the long-term needs are really best identified by the people in doing research within the regulatory agency who are in close association with the research and who can predict these long-term needs.

Some of the problems—there is, for instance, recently Congress under RCRA passed a law which had what we call hammers. They had certain dates by which things had to be done. We basically took a laboratory and turned that laboratory around from what it was doing to do something else within a given timeframe.

Now, I would disagree with Dr. Hendrie that you can't rush the research. This is research that, because of the needs established by

a congressional mandate to develop the ability to model the rate of flow of materials through earth, this is work that was done much more rapidly and appropriately done, I think done with good science.

If we are going to talk, however, in situations where we are asked to do something for which the science is not ready, then absolutely correct. There is no way that you can, in a sense, get that science to move more quickly than it can. We need to know too many things. We can make some changes on the fringes, but by and large you are not going to move it more quickly than the science can move.

But in many of the areas that we are dealing with, the ability to do the work is there. It is a question of where you will put your resources for that work. In my experience in managing sciences and my experience in being someone who is a researcher being funded by Federal Government agencies, I can assure you that it is a lot easier to take a Federal laboratory and say, "Look folks, we have to drop what we are doing and do something else within your capabilities for that answer because Congress has required it," than it is to get outside scientists to do it.

One of the things that I was fascinated with is that laboratory—and this is a laboratory in Athens, GA, that was asked to do this—by and large responded very positively to doing that, to dropping what they were doing, something scientists usually don't like to do. Of course, they saw the real need for it, were given the attention and the funding to do this work, and they found it a very stimulating thing that needed to be done. They wouldn't have done it right then. They would have done it some other time.

So, that was a very positive experience, and I don't think it can be done elsewhere.

Mr. WALGREN. Mr. Jorling?

Mr. JORLING. I think Dr. Hendrie's first point is a large measure of the explanation, the different traditions of the two agencies. Without going into that history and the performance of the research and whether there are real differences in the kind of research that is done, I do think it is essential that scientific and research and development arms of an agency be as responsive to the mandates of Congress as is the regulating branch and that good management can bring that about.

Typically, EPA requires, unfortunately,—and this is not unusual to any administration; that is the way it is—2 to 3 years to take a Congressional mandate and put the first set of regulations into the Federal Register. My argument is that with the right kind of management and leadership, that effort can go on involving the science and the analytical people conjunctively and get to a reasoned and good public policy result.

Mr. WALGREN. Thank you.

We have to respond to this rollcall on the floor at this point. I would ask if you could stay and we will come back to you. There are a couple of areas that I know people who have thought about this have tried to direct our attention, and I might be able to raise some of that with you. So, if we could take a 15-minute break at this point and then if we can come back at that time.

[Short recess taken.]

Mr. WALGREN. Well, after that, I thought I had some great ground to cover and my mind is not up and running.

How do you reconcile what I hear Mr. Jorling saying that instinctively there is a short-term ability—Dr. Goldstein says the same thing—there is a short-term ability to respond to regulatory problems if the resources are directed in that direction, and what has apparently been said to be a failure of the regulatory agencies to develop a longer-term basic research program are these two different things that should be done? Regulatory agencies, I guess, should do both?

Is there reason to have these very separate so that perhaps you can force the interface with the one but perhaps have some of the separateness that Dr. Hendrie emphasizes with the other? Are we properly criticized for being too short term in the regulatory research programs? Is there a basic inconsistency between doing both? Is there an ability to do both?

Can I ask for brief reactions to that thought?

Dr. GOLDSTEIN. Let me in a sense try to put an additional dimension on the question you are asking, sir. I think there is a need to do both.

From the EPA's point of view as responsible for EPA science and technology, it was important to recognize that in certain areas, such as in health, EPA's health research is a tiny, tiny percentage of the overall health research done in this country. If EPA's health research disappeared, the Federal health research would not notice it. EPA would notice it.

On the other hand, if you get into something like atmospheric transformation, if you get into an area such as ecology, effects of pollutants in estuarine areas, EPA had a major portion, a significant percentage of total Federal and total, in fact, U.S. research in that area that it was supporting.

It was much more important for EPA to be doing long-term research in those areas in which it was, not the only player, but a substantial player than it is in those areas where EPA is not a substantial player in the totality of that type of research. So, the answer is yes, both are needed, but the degree to which we need both will depend in part upon the resources that are available in the total U.S. research effort.

Mr. JORLING. They are two different functions, and I believe that the short-term one, the one that is under the mandate from Congress, is the more important one for EPA to be carrying out. However, I strongly support a portion of EPA's R&D effort being devoted to long-term research.

I would qualify that, however, by saying that participation in the short-term processes of the agency enable perception of and identification of the most likely important areas for long-term research more than just sitting back as a group of experts and trying to anticipate what the long-range needs are. They can be drawn out of the short-term processes much more accurately, much more relevantly than they can otherwise.

Once you recognize that, I believe an agency like EPA should have a residuum, under the direction of the R&D arm, which is devoted to long-term research. In EPA's context, however, I don't think that would be a very significant proportion of its research.

Ten percent would be a nice target. It is below that right now, I think.

Mr. WALGREN. That would vary from agency to agency, I gather, depending on their role?

Mr. JORLING. Yes.

Dr. HENDRIE. Mr. Chairman, I think there is no question that a regulatory agency needs both. In the atomic energy business, we have always pretty well separated them. At the NRC, we had a major research program under an Office of Research that was engaged in long-term, more basic and thorough-going reactor safety studies and associated science and technology to support that.

The short-term assistance to the regulators and the licensing staff came under the heading of technical assistance. Those people in the agency had contract authority to establish contracts with anybody they thought was competent to help them and that work they ran themselves. That we regarded as just what its title implied—technical assistance to the regulatory and licensing staff. That was of a short-term response to the problem sort of enterprise.

But for the most part, I don't regard much of that as science in the sense that I think you are talking about it here. The science in the NRC is almost completely over in the Office of Research, it is long-term, and it needs to be done by people who keep their minds on those long-term projects.

Mr. WALGREN. Is there a difference in the importance of these agencies having their research in-house versus contracted out? Would that be something that you would agree that you would find most appropriately substantially different balances from agency to agency, or can you categorically say that you prefer the capacity in the organization or essentially contracted out?

Dr. HENDRIE. I think I will say categorically that I think it is better if you contract it out simply because you can go to the best people for a given piece of work, and you are not saddle with a certain number of slots which are labeled research who are there year in and year out, immovable as the Federal personnel policies make them. Once you get them, you have them for life unless they decide to take themselves off.

On the other hand, you must recognize that I speak from an experience that is totally the other way. It is my view that it is the better way to run it, and it is my view that EPA could very well have established a contract research program in the beginning and developed a set of people in the universities and in research institutions and all around the country whom they dealt with principally and things would have gone just fine.

I remind you again that is a view which is based on my own experience in that kind of system. So, you have to take the answer and weigh it with that background and prejudice in deciding what is best.

Mr. WALGREN. Well, let me ask Dr. Goldstein. You indicated in your testimony that you felt that EPA had lost a certain amount of flexibility particularly on the question of where the research was to be done. What led to that? What lies behind that problem?

Dr. GOLDSTEIN. That really is a bureaucratic problem, sir. I have no real difficulty with the basically 2-to-1 split in favor or extramu-

ral versus in-house research that the budget has given us in the past few years. I might prefer it to be 60–40 but it is an appropriate range. Most of EPA's research is done extramurally.

But because of the fact that really micromanagement has been performed by congressional staff, OMB, within the agency on controlling the way the budget is used, there simply isn't an adequate amount of money to fund the 1,800 people who are provided to us under the budget. So, we don't have enough money to buy our rats. We don't have enough money to—I say we as if I am still there—but there is an inadequate amount of money to really do the research that has been budgeted agreed to by Congress and the executive put in there, and it is because of a budget process that is inappropriate.

I can go into it in great detail if you wish. Perhaps let me just say one other thing. The way the budget is made, there is an internal salaries and expense budget. Only in EPA is that budget, which is under congressional wording of the resolution for managerial purposes, only in EPA is that also for in-house research.

There is another budget called research and development. In NASA, for instance, they use that research and development in-house or extramurally as they feel warranted. In EPA, we must use it extramurally. We cannot use it intramurally.

The net result is that since you must pay the 1,800 people, you must pay the money to keep the laboratories open, the amount of S&E that is left over after you have done those two necessary things is the amount of money you have to buy your rats to do the other research needs. And that has been grossly inadequate, and it has been going down. So, during my tenure at EPA, starting at $230 million budget now being over $300 million R&D budget, I actually had a decrease in the amount of money available for those scientists who were doing in-house research simply because of the sort of backward way that that Research and Development Program was put together with this unnecessary degree of micromanagement.

Mr. WALGREN. You used the phrase to buy your——

Dr. GOLDSTEIN. To buy the rats. Experimenters have to buy rats.

Mr. WALGREN. Oh, to buy rats. I see, a generic term.

Mr. Jorling, would you like to comment at all on that?

Mr. JORLING. One of the things that we all deal with in public life is that we are saddled with a bit of history and it is not possible to look at the blackboard as if it were blank and recreate an ideal scientific research and development arm that would be applicable to all agencies. We are stuck with the histories of each of these agencies.

AEC started with a very different history, especially with respect to science and research, than did EPA. When EPA was formulated in 1970, it was an amalgam of several other agencies and the laboratory structures that were in those agencies came in to form the basic structure of the EPA Research and Development Program.

So, there is a different history and any changes which I would call should be directed more at incremental improvement rather than trying to recreate a nice new structure that might be nice for the tidy-mind syndrome but wouldn't really reflect these different histories.

On the contracting out, I indicated in my prepared remarks that I am very negative on that, partly because of what I consider to be inherent conflicts of interest that exist in our context which is different than the context of NRC's laboratories which are, while they are contracted out, they are in effect a sole-source entity out there and a lot of what they are avoiding are salary limitations so that they can pay their scientists much higher than the civil service can pay them. But they still have some attributes of responsiveness that the contracting relationship that EPA uses is not available.

So, there are those kinds of differences.

The contracting procedures, the contracts themselves make it difficult to change anything that is going on as change is perceived to be needed by policymakers. So, there are a series of reasons why contracting out is insufficient.

I would shift the percentage the other way. I would go 60–40 the other way if EPA had sufficient in-house personnel to manage those contracts, manage them in more than just a paper volume sense but actually manage them to make them responsive to the needs of the agency. But right now, I don't believe, certainly it was the case when I was at EPA, that the agency had sufficient personnel to make sure that those contracts were delivering the kind of service that the agency needed.

So, there are a lot of impediments, but I tend to believe that the agency can attract the best and the brightest even within a restricted salary structure and that is not a real impediment.

Mr. WALGREN. You all sort of indicated an approval of the distinction between risk assessment and risk management and the separation—or perhaps I am putting words in your mouths now—but someone touched on that and I thought there was something supportive said in that direction, the one being a purely scientific risk assessment and the other being a political question of risk management.

How good is our risk assessment? Does it really give guidance to those who are then proposing methods of management?

We had a bill up here in this committee that was intended to try to stimulate some thought on that, and on the question of what a model risk assessment should look like. You get the feeling that the assessments are often simply the supportive opinion for whatever conclusion somebody wanted to reach.

Can you tell me where we are on risk assessment and are there separations that can be made effectively between assessment and the response to it that we could receive in a way that you could distinguish between the two and perhaps reach different conclusions from it?

Mr. JORLING. I will respond, Mr. Chairman, just by suggesting that I could submit for the record an article I have written on that precise subject and defer to that. I think it is better expressed there than I can do orally.

Mr. WALGREN. OK. We are certainly interested in that.

[Article by Mr. Jorling follows:]

Risk Assessment: Dissent from a Former User

By Thomas C. Jorling

In the dynamic area we call public policy, new themes and new words and phrases emerge frequently, though usually in unpredictable ways and with uncertain impact. Sometimes these changes in our rhetoric reflect new thought, new ideas or new concepts; sometimes they merely represent, as it were, a new name for rose; sometimes they are a little of both. Risk assessment and its corollary risk management, while not new terms in the strict sense, are certainly new to the public dialogue in environmental protection. There may be some new substance behind the term risk assessment, primarily as a function of the whole representing something more than the sum of its parts, but the words do little more than provide a new lens through which to look at old, reliable, in the sense of constancy, environmental and health protection concepts, policies, and issues.

Just the fact of changing words and phrases — even before we look behind them to what they describe as I propose to do on risk assessment — can operate to real effect. For instance, new words can attract new interest, or rekindle old interest in a continuing problem. The press may cover a story on "risk assessment" when they wouldn't be motivated to cover yet another story on "pollution control." However, on the other side of this two edged sword, a change in words can provide an affected interest with another bite at the apple, as for instance, when a statute, directing pollution control more tightly than an affected interest would like, might be revisited under the guise of this new thing — risk assessment. Of course, this is, in one sense merely being clever in the competitive processes of public policy development.

But we shouldn't lose sight of the fact that a change in the semantics of public dialogue is rarely benign in effect, if not in intention.

One would gain the impression from reading both the popular and trade press and even the scientific literature that risk assessment is an overarching concept that includes within it all aspects of environmental protection; a new paradigm. As such an impression, it is wrong. Risk assessment is a tool, but in the sweep of issues that flow from the relation of Homo sapiens to each other and to the environment, it is — and should be — a limited one. In this article I propose to examine what risk assessment is, and isn't, from three perspectives; first, its use as a conscious and unconscious diversionary concept; second, its limitations when used in public policy processes; and third, its pragmatic and important use in the traditional decision making process.

Among the primary obligations of the governments' of industrial societies is the establishment of policies and programs that assure the integrity of the structure and function of the life supporting biosphere into the foreseeable future. A future that should extend at least as far into the future as we can see our past — several hundred years. Risk assessment as a policy does not contribute materially to that fundamental objective. More significandy, to the extent it is held out to be such a policy, it diverts attention, and more significantly, effort from the primary objective.

Risk assessment is premised upon and assumes the release of chemicals to the environment. As a general principle describing the dynamics of industrial society that is a flawed assumption especially when considered from a perpective of hundreds of years. A policy of reacting to releases after they occur, in a society where chemicals are introduced at a rate of several thousand per year and where quantities of production have grown from mere millions of pounds of production in the 1920's to over 400 billions of pounds currently, is simply irresponsible. There may be situations where a given chemical "must" for compelling reasons be released, but to assume all chemicals can be subject to risk assessment and then released at an acceptable rate runs into the face of the complexity of the dynamics of public health, much less the complexities of ecosystem dynamics.

Thomas C. Jorling

The overarching quest, the guiding policy, must be to prevent release, to move industrial systems in the direction of closed cycle production, recycle, reuse and confined and contained disposal of pollutants. The challenge to our production engineers and our product developers is to create ways to prevent release through such principles as separation of production processes, change in processes, conservation in the use of matter and energy, segregation of waste streams, and source control. We can over time and economically achieve these results. For instance, under Clean Water Act program of effluent control more than fifty industrial categories have reached elimination of discharge.

Even in the area of combustion, while there will be releases of carbon dioxide and water that, especially in the case of CO_2, may cause disruption of the life support system, fuels can be cleaned, combustion process and facili-

Thomas C. Jorling served as Assistant Administrator of the Office of Water and Waste Management of the U.S. EPA under the Carter administration. He is presently director of the Center for Environmental Studies at Williams College.

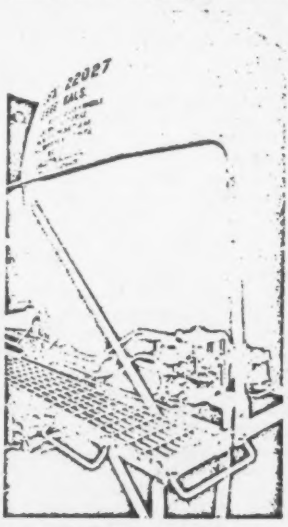
"Risk assessment is premised upon and assumes the release of chemicals to the environment. A policy of reacting to releases after they occur is simply irresponsible."

ties can be engineered, and recovery systems can be installed to prevent release. The notion that a rapidly increasing, rapidly industrializing 4.5 soon to be 7 or so billion people can acceptably load the biosphere with chemicals is not only wrong, it is unnecessary. An automobile, if designed at the outset for the recovery of components at the end of its useful life could easily serve as a source of metals, plastics, and fibers for the next generation. In addition to preventing the release of chemicals to the environment, this pattern of product use would abate the tremendous waste that is characteristic, so far, of all industrial societies.

When the Administrator of EPA — even if unintentionally — carries forward the message that the basic role of EPA or the Government is to conduct risk assessment and its corollary risk management it diverts our energy from the basic responsibility to move toward a society structured and functioning as if there is a tomorrow. In my view, the response Mr. Ruckelshaus has received from such sources as Mobil Oil Corporation praising risk assessment[1] is a manifestation of this diversion. As representative of corporations charged with the duty to act in the best interest of the corporation, Mobil does not want to spend in the interest of the future of society. Mobil recognizes risk assessment assumes releases of pollutants, and that with their expertise they can in all likelihood demonstrate "acceptable" risks associated with their pollutants. I will say more about these implications in the second part of this paper. The diversion, however, has worked. It has shifted the focus to risk assessment not as a tool, but rather as the end. It makes it all the more difficult to organize ourselves in a manner that will assure a long-term sustainable society. Our intellectual genius instead of being applied to avoiding releases of chemicals to the environment will be caught up in the never ending task of figuring how much chemical, in a world of an ever expanding increase in the manufacture and use of chemicals, can be packed into the environment with acceptable risks.

II

The new EPA Administrator, William Ruckelshaus, has made risk assessment and management a central theme in his effort to put distance between himself and his immediate predecessor, Anne Gorsuch Burford. Understandably, Mr. Ruckelshaus needs to change the dialogue concerning environmental protection if he is to reestablish any credibility for EPA and its mission. In his campaign, with addresses to the National Academy of Sciences, and articles published in such distinguished Journals as *Science*,[2] he is attempting to seize the



A rail car designed to reduce the risk of accidental chemical spills.

high (rational) ground and his weapons are risk assessment and risk management. He describes the concepts:

> "The formula should be as precise as possible and should include a responsibility for assessing the risk and weighing it, not only against the benefits of continued use of the substance under examination, but against the risks associated with substitute substances and the risks associated with the transfer of the substance from one environment medium to another through pollution control practices."

and a little later on:

> "Scientists assess a risk to find out what the problems are. The process of deciding what to do about the problems is risk management. The second procedure involves a much broader array of disciplines and is aimed toward a decision about control.
>
> In risk management it is assumed that we have assessed the health risks of a suspect chemical. We must then factor in its benefits, the costs of the various methods available for its control, and the statutory framework for decision."[3]

While there are exceptions in its actual applications, such as in pre-manufacture review of chemicals under the Toxic Substances Control Act, most applications envisage by the Administrator are to ongoing activities or often to activities that have been initiated that result in the release of chemicals. While the words risk assessment are new, when applied to such situations, they, in fact, describe what is an old pollution control concept — that of ambient control strategy such as that represented in general by the Federal Clean Air Act. That is, find out (who?) how much of a chemical we (this or that generation?) can accept in the environment, to take advantage of the benefits of the use of such chemical (what is the value of a few lives lost?), then apply and maintain controls to achieve that level of release.

Risk assessment and its semantic antecedent, an ambient control strategy, share many flaws when advocated as a public policy that need to be understood. First of all, it puts the entire burden of proof on the government, on the public and the environment to support control.

It is not just a burden of proof in a legal, evidentiary sense. It is a burden that is made exceedingly heavy by what it in fact assumes. It assumes an ability to acquire knowledge about the release of chemicals, their transport and fate throughout the biosphere, their effects throughout the myriad of organisms in the biosphere, over time, and ability to evaluate possible synergistic effects. If we are concerned about the health of persons, then we must in addition incorporate all of the uncertainty on how and why chemicals reach, and then effect the structure and funciton of a human organism, an organism

"When the Administrator of the EPA carries forward the message that the basic role of government is to conduct risk assessment and risk management, it diverts our energy from moving toward a society structured and functioning as if there is a tomorrow."

already immersed in an environment with countless chemicals in countless circumstances. But risk assessment all sounds nice, because as the Administrator assures us, scientists do it. And before you make a bumper sticker out of the preceeding — the phrase "for money" should be added.

Each of these elements of the burden of proof deserve attention. The ability to acquire knowlege about the release of chemicals into the environment assumes a monitoring and analytical methodology that is not, nor will soon be routinely available. Whether in air, water, or solid waste streams we generally only sample for the most gross parameters. Where a given chemical is targeted, specific methods and protocols must be tailor made — always with the burden on the government, constantly scrutinized and contested by the affected interests. It's one thing to say scientists do it, it is another to ask whether they can.

Once released, understanding the pathways by which chemicals move through the biosphere, how they interact and with what effect on organisms is assuming that we can know in detail what many ecological scientists believe is a system — the biosphere — that is more complicated than we can think. Yet, if we assume the release of chemicals — we willingly take on that burden.

Time, and the effect its passage causes as chemicals are released and move through the biosphere is over the edge of uncertainty. We may know what a given chemical exposed to an organism or community of organisms does in one day or one week or one year, but we know precious little what it may do after ten years. Yet, such an understanding is implicit in carrying the burden of proof in a risk assessment that may lead to the authorizing of the release of certain concentrations of that chemical for many, many years.

Synergistic effects, that is the action of one chemical as it may be influenced by the action of others — probably hundreds of others — is currently outside of our understanding. We generally caveat any statement about a chemical subjected to risk assessment by simply stating we do not know what the synergistic effects are, if any, in any of the countless situations as a given chemical moves through the biosphere.

These limits, or perhaps better elements of the burden of proof take on added importance when the target organism of the risk assessment is the human organism. The use of risk assessment as an overriding policy as it appears the new Administrator is urging when he advocates the modification of the Nation's environmental protection statutes to incorporate risk assessment as "a common statutory formula for accomplishing our tasks"[4] necessarily involves the ultimate experiment — it would use the American people as a population of experimental animals. Since we do not use humans in direct exposure experiments, we rely on surrogate animal and other tests (and often the regulated interests strongly oppose these tests). Scientists simply can not do more than estimate risk. Risks deemed acceptable by such methodologies are then tested on the people.

With these and many other uncertainties and weaknesses inherent in risk assessment, the problems for public policy are compounded when we move to the application of risk management, which is basically the application of benefit-cost principles to decisions on whether, and to what level, a release of a chemical should be controlled, i.e. the determination of an end, not of means.

There are many criticisms of benefit-cost methodologies, especially when applied to make choices among ends, rather than among means. I will not repeat those but add some that are not so common.

Let us look at some of what I believe to be essentially related implications of risk management with its necessary inclusion of benefit-cost methods. Mr. Ruckelshaus describes it as follows:

> "in risk management it is assumed that we have assessed the health risks of a suspect chemical. We must then factor in its benefits, the costs of the various methods available for its control, and the statutory framework for decision."[5]

It is argued by the proponents of such analysis such as Murray Weidenbaum, President Regan's first Chairman of the Council of Economic Advisors, that it is "a neutral concept: the same weight is given to a dollar of costs as to a dollar of benefits."[6] This notion that all aspects of life can be reduced to the same measure — a dollar — is neither neutral nor objective. Rather, it flows from a preceeding ideology — about which more will be said later — that humans are motivated *only* by that subset of activities that generate monetary wealth.

It does not take an extraordinary display of human judgement to conclude that a five dollar heart pacemaker component is not "worth" the same as a five dollar can of deodorant, or that an issue of *Governance* at $3.00 is "worth" the same as an equivalently priced issue of the drug cultures publication *High Times*. However, once those numbers are entered on the benefit-cost ledger they are rendered "equivalent."

But this dogma of faith — or fiction — that everything can be compared through the measure of dollars is compounded in its effect by the systems or methods through which it is applied in so-called analysis — and further removed from human judgement. Increasingly, the analysis part of risk management is performed by the computer — which even if humans can't agree on value — *must* compare everything — apples and oranges — as if the dollar does in fact compare the value of everything. And in the end, it punches out those all too intimidating printouts: "see, its right here in the numbers, the benefits outweigh the costs." Human judgement is avoided in relying on the hard, objective numbers — "the bottom line."

We can distinguish the type of benefit-cost analysis used, for instance, in choosing among building materials. There it makes good sense, it is being used as a tool to assist in a choice between means. This brick with a cost of such and such and benefits in terms of strength and durability versus another competing material. But to compare dollar benefits to the economy of the chemical XYZ used in making eye shadow against the dollar costs of a slightly increased cancer rate in the society cannot by any mixmaster, cuisinart or not, be made the same.

EPA technicians remove a sample of hazardous waste from leaking drums.

Wendell Barry has put it more succintly: "The viciousness of a mentality that can look complacently upon disease as "part of the cost" would be obvious to any child. But this is the "realism" of millions of modern adults."[7] Charles Dickens said a fool is some one who knows the price of everything but the value of nothing.

Another, and not benign element of the ideology that must be evaluated in considering the efficacy of the application of risk management to broad questions of public policy is the general underlying premise that whatever increases monetary wealth is inherently to be preferred over those things, activities, or experiences that do not. And it is not only preferred, but induced by such analysis. So that directing effort to caring for a retarded child, for instance, appears irrational to benefit-cost analysis especially compared to a professional baseball player or even a drug dealer. Not only does risk management incorporating benefit-cost analysis favor strongly wealth creating activities, in the sense it gives them more "votes," it also strongly favors, also in the sense of giving them more "votes," those persons, real or artificial, and activities that possess, control, or involve large amounts of resources that are, or are easily converted, into dollars. Thus, for instance, any constraints on highly consumptive lifestyles, such as frequent flying would represent a huge cost, while restraining the use of automobiles by the poor would not, or improving controls in a chemical factory would represent a large cost, while the value of the health of people in the ghetto would not. If everyone had the same number of dollars it may be that — as in the one man one vote democratic theory — the use of benefit-cost analysis would represent an approximation of how persons valued different courses of action, but they don't and it doesn't.

Since risk management represents a systems technique it is useful to raise another concern that flows from the rigidities created by systems phenomena. Benefit-cost analysis is advocated as technique for evaluating an action or a proposed action in our dynamic sociopolitical system. If benefit-cost analysis becomes the formula applied to public policy decisions as advocated by a broad spectrum of economic theoreticians and practitioners ranging from William Nordhaus, a Yale economics professor and former economics advisor in the Carter administration, commonly identified as a "liberal" to Murray Weidenbaum, identified as a "conservative," then it would assure that our system would not change its basic orientation for, by definition, any change in the system would be an unacceptable cost. We can be thankful that the Declaration of Independence and the Constitution, much less the recent Civil Rights and environmental and health protection successes preceded this new methodology. It is unlikely any would have been produced, only if the benefits exceeded the costs.

The driving orientation implicit in benefit-cost analysis — is, simply put, the maximization of material greed. It measured all things in terms of dollars and since the unit of comparison can and does grow, it follows that those activities or behaviors which lead to more dollars are going to be the activities or behaviors that the method of evaluation will favor — nay, by its own terms it will serve, in a vindication of B.F. Skinner, as a reward to elicit that kind of behavior.

Adopting a system that reduces all features of human actions and values to expression as a unit of commercial value *necessarily* degrades those actions and values which do not contribute to an increase in those units. Merely being in good health does not, nor does love, nor brotherhood, nor appreciating beauty. Over time in such a system therefore, the relative value of those characteristics must decrease. A benefit-cost system will certainly produce an efficient commercial machine, and those human values inconsistent with that result will, per force, be eliminated in the process.

The protective regulations under mandate from Congress flow from a sense of justice and compassion, from a principle that it is wrong for innocent citizens to be exposed to threats by

"The people will understand and accept risk, not when government is acting to protect the activity leading to the risk, but when the government and the authority causing the risk are moving to eliminate it."

activities over which they have no control, and in many instances, of which they are not even aware. It was a response of society that emanates from a traditional view that the welfare of human individuals, all human individuals, is the primary reference measuring all activities.

But now regulation is a practice subject to criticism and challenge on many grounds. I am not referring here to the criticism that regulations can be made somehow 'better' or developed with less reliance on red tape. I am concerned with a popular assertion, and an apparent 'cause' of this Administration, that such regulations should be applied only if benefits outweigh the costs. Sometimes explicit, but always implicit in such a premise is the result that previously considered "inalienable rights" are now subject to being commercially valued and then lossed or gained as a consequence. Life itself would be valued and while the exact identity of those who will suffer death is not known, especially to the practitioner of the analysis, the death of real human individuals will occur.

Some argue this phenomenon is simply an inescapable consequence of modern, technologically-based societies. But cutting away all the rhetoric, this reduces to a view that technology doesn't serve humans, humans serve technology and its imperatives. It is as if the relatively benign feelings of the B-52 pilots causing untold and unbearable destruction from their plush offices high in the sky are an inescapable and presumably better aspect of high technology, while the feelings of the G.I. pulling the trigger on a proximate and recognizable human are mere relics or artifacts of the past. In many ways benefit-cost analysis performs the same role as the B-52. It immunizes from human relationships by placing distance and technology between action or decision and consequences.

III

This then leads to my third point. Risk assessment is a valuable public policy tool and is, and should be, used as such. It is not, in my view, an overall strategy or goal for environmental protection.

Administrators must decide among the very large universe of problems contesting for attention which ones should receive attention and especially attention in the form of scarce resources. Frequently, EPA is faced with choices such as should it apply its resources (R&D, regulatory, financial, staff, etc.) to this or that chemical, this or that geographical area, or this or that hazardous waste site. Risk assessment is a most necessary tool in informing that decision.

Similarly, in any real world situaiton prior to achieving closed cycle production and recycle, reuse of materials, EPA and other agencies must make judgements on interim levels of control or protection to be achieved. Risk assessment can guide, not make, that judgement. But, readers must be saying, this sounds very much like the Ruckelshaus' articulation of risk assessment. And so it does. In the day to day life of environmental protection these activities do and should go on. They have been going on since the beginning, we just now call it risk assessment. And when it does go on it should go on with the best science, the best analysis, and, of course, the most open and candid communication with the public. On these points there is no disagreement.

The dissent from the Administrator's view comes at the next stage — the stage of risk management — where the practice becomes not just a tool but the objective — i.e. to define acceptable risk from a given practice as the end point of environmental protection. It is no wonder that many responsible for the release of pollutants, such as Mobil, become supporters, when risk assessment/management take on this character. But, as I have tried to point out, risk assessment must take place in an overall policy of achieving chemically tight industrial societies. We must force continued development of industrial processes that don't release chemicals, of products that can be recycled, and of wastes that can be contained. National policy must force technology to these objectives, not as a risk assessment and management policy necessarily does toward an objective of dictating for the public an acceptance of risk for all time.

In my view the people will, for a peroid of time, accept a risk, identified by the government if they have a credible belief, one, in the competence and honesty of government and, two, that the overall program under which our society is operating is designed to avoid that risk. The people will understand and accept risk, not when government is acting to prorect the activity leading to the risk, but rather when the government and the authority causing the risk are moving to eliminate or further reduce the risk.

Put in a more immediate context, the people near the Tacoma smelter may accept, or the government may impose, a risk after the installation of the best control and process technology if the smelter and the government have underway a meaningful (i.e. real research dollars) program to improve the smelting process and the technology of control and that the decision on the level of control will be revisited in five or so years with improvements in control or process, if any, then imposed on the plant.

To summarize then. Risk assessment and management is a valuable tool in making decisions on what to do at any point in time, or on what chemicals or activities to focus scarce resources. It should not be an overall policy for environmental or public health protection. If it becomes so we will have lost an opportunity to work toward an industrial society structured and functioning as if future generations make a difference and if such concepts as life, liberty, and the pursuit of happiness are to continue to have real meaning. □

Mr. WALGREN. Are there any other thoughts on that?

Dr. GOLDSTEIN. Having spent a fair amount of time in the past few years working on this question, let me just briefly if I can give you an overview of my view on it.

I think risk assessment is a very valuable tool, but a tool for the regulatory process. Like any tool, it has its limitations and the best use of it is made when the worker really understands how to use the tool.

We have had some problems with it. I have been amazed sitting in at decision meetings where there have been three numbers on a blackboard. One is a risk assessment number of, say, a body count. Another has been an economic cost of doing something about that. The third has been a guess as to what the economic costs would buy you, what the control would buy you in terms of decreasing the exposure. There are tremendous arguments about whether that risk assessment number is correct or useful.

In fact, there is a lot of uncertainty about that one number put on a blackboard, but I didn't find it any more uncertain than those other two numbers, the economic analysis, that guess as to how much control you would really buy if you put on this new installation or new device or tailpipe or whatever it might be.

So, in the context of the need for a regulator to make a decision with the kind of number that regulators have with which to make decisions, I find risk assessment to be very useful. Now, in the context of is there actually going to be 37.37 people dying each year because of this particular pollutant at that particular level, obviously that is not an exact number and obviously it has many difficulties, but I don't find it having more difficulties than other numbers.

In terms of the risk assessment and risk management separation, the need to keep the risk assessment from being the number that the risk manager wants to get which I think is crucial for the success of this, it can be done. At EPA, we have tried to come up with guidelines on how to do risk assessment. The guidelines are the best available science that we know now. They are not only logical in that sense, but they are explicit.

If you follow those guidelines, you will come out with an answer. If you don't follow those guidelines, you explicitly have to explain why so that if, in fact, the scientific community will agree with it, that is fine. If not, you basically can appropriately be accused of distorting the process.

So, in general I find that separation can occur. Guidelines are useful, and it is valuable. The separation is not complete. The risk assessment process in terms of hazard identification, quantification of dose response, exposure assessment, they can be separate from risk management.

But when you take all those numbers together you get a risk characterization. How you characterize that number that comes out starts to get into the risk management point of view. As a physician, I do this all the time. There is a test that has a 1 percent incidence of side effects. Do I say to you, look, if you take this test there is 1 percent chance you are going to die of it, or do I say to you it is 99 percent free of risk?

That is a characterization that can also be used in the risk assessment process and the end point of the risk assessment process which we have to be careful with. There is also more to safety considerations where it is not clear whether that is risk assessment or risk management, to what extent a margin of safety fits into that. But, by and large, you can keep them separate.

Mr. WALGREN. The concept of risk characterization, is it right to think that there are some circumstances under which there will be a certain number of bad results? You don't know which individual result will be a bad result, but there will be a certain number of bad results. Does that characterization—is it fair to say that is one kind of risk, a risk where we don't know whether any individual will be harmed or have a certain effect but we know some individuals will and we can make a pretty educated guess about how many individuals will and that is one characterization.

Another characterization would be the possibility that some will. Maybe none will. In my mind, I keep flipping in and out on those two where in one instance, there is a short straw in there and we just don't know who is going to pull it. In the second instance, we don't know whether there is a short straw in there but there might be.

Does risk assessment differentiate between those two kinds of——

Dr. GOLDSTEIN. Yes; and I think you have phrased it very well. The hazard identification process, if you will, allows us to say there is or is not a hazard there. When you can say there is or is not, that is fine, but when you say there may be a hazard there, that is a problem.

What we did at EPA in the last year or two is to put a letter next to the risk number we get out, the letter indicating whether this is known to occur, suspected to occur, possibly might occur. We can use different adjectives. But how you characterize that, as you have just done, is part of the risk characterization process once you have that information. Obviously, how you present it to the Congress, to the public, to the regulators is going to make a difference in how people respond.

What we feel is important from the risk assessment, from the scientist's point of view is that we be asked to always present it in the same way, but that really, if you will, it is the managers' role to tell us what is the way that they want it presented so that you always do it the same way across all different types of chemicals and situations, and we don't one time present it one way and another time present it a different way, one time say it is 99 percent and the other time say it is 1 percent.

So, we have asked for that type of help.

Mr. WALGREN. Dr. Hendrie, is there anything you would like to add?

Dr. HENDRIE. To your basic question, Mr. Chairman, I think risk assessment methods have been developed and improved substantially over the last 20 years and they are getting to the place where they are very useful. It is still an art which depends in part on the skill of the practitioner, and that is a human variability that you have to be very careful about. But I think one can make in a number of technologies and in a number of areas there are meth-

ods of doing risk assessment that give you a much better handle on what the risks in that area really are than any other way that I know of approaching the problem.

In particular, risk assessment methods are a very useful way of disciplining your approach to a problem to try to keep you from omitting things on the one hand or giving undue emphasis on the other to a certain special aspect.

Risk management is what we are doing in safety regulation. Safety regulation, in my view, is intrinsically an exercise in risk management. So, they are separate but they obviously have strong relations.

As has been pointed out by my colleagues here, once you begin to talk about an area in risk assessment terms, you begin to create a language and a way of thinking about that area which is almost certainly going to be reflected in the risk management in the regulation area.

Mr. WALGREN. Well, I am intrigued with the difference in the character of those risks in that politically, I believe, these days you often hear nothing is risk-free, therefore justifying the individual to run a certain risk. But from a public responsibility level where you really are responsible for the whole, there is a very real difference between—it becomes irrelevant or relatively irrelevant whether any individual is running a risk. The real question is what is the certainty of the harm in the aggregate.

If you have a problem where there is certain harm in the aggregate, it seems to me that we should approach that very differently from a problem where we only have possible harm in the aggregate. Yet, I hear arguments that, from my opinion, are urging the public that, look, nothing is risk-free; therefore engage in a pattern of behavior which, although we said it isn't risk free, it was only risky to the individual; it was certainty to the aggregate.

Dr. HENDRIE. I don't find the dividing line that you seem to find, Mr. Chairman.

Suppose I know that exposure to ionizing radiation produces—I have a statistical basis for believing that there is a connection between exposure to ionizing radiation and certain latent forms of cancer. I have determined within the limits of error of my statistical analysis that we will get a cancer with every 5,000 man-rem of exposure in the population.

However, the uncertainty range on that result runs from 0 to 2 cancers. It may be 0. Nevertheless, I have a frequency distribution which says the likelihood that I will get 1 cancer for 5,000 rem is higher than that I will get 0 or I will get 2 or any higher number. There is a frequency distribution, and in deciding what policy ought to be with regard to ionizing radiation exposure, I can look at the frequency distribution which includes 0——

Mr. WALGREN. Why does it include 0? It may very well in that instance, but are there instances where you might be more likely to get 5 and your uncertainty range runs from 2 to 7?

Dr. HENDRIE. Well, in this case it runs from 0 to 2.

Mr. WALGREN. Yes, but hypothesize with me an instance where it ran from 2 to 7. You could step back and say you are sure you are going to get 2; you most likely get 5 and you might get 7. That

is a different circumstance than the circumstance that you raised as an example where truly you could say we may get none.

I am wondering, in the regulatory business, are there these two kinds of circumstances or have I made one up?

Dr. HENDRIE. I dare say there are some places you find where you could say my assessment, even though my precision is not ideal, there is a frequency distribution in what I understand about the phenomena, but I have very high confidence that there will be some effect, that is, that the wing going toward low values either doesn't get to 0 or when it gets there it is a diminishingly small likelihood.

But I suspect that there are also an awful lot of areas where the wings of the distribution on the low side go in fact down to 0. They certainly do for low level radiation. There is no question about that.

Now, what do you do about that? Well, you look at what the distribution is and say, look, the most likely value, the place that it looks like a more probable result lies isn't at 0. It is up at 5,000 rem and there is an effect and we will now take regulatory steps and establish some requirements that take that into account.

You do the same if the center of the distribution is up at 5 or 7 or wherever you like. So, the fact that the wings go out to 0, I don't find that creating a qualitatively different situation to deal with from a safety regulation standpoint.

Mr. WALGREN. I see. Are there any other thoughts on the same situation?

Dr. GOLDSTEIN. No. I think in a sense the kind of problems that we know of that we can definitely identify a number are, unfortunately, the easier ones. You ask me if we put the mall into wildflowers how many people would come down with hayfever or asthma attacks from the pollen, I can come up with a number, and I can assure you it won't be 0. Workplace allergens, seatbelt rules—we know that there will be people dying in automobile accidents no matter how we alter that risk.

But most of the chemicals that we deal with that are uncertainties and where there is major argument about them, the probability distribution goes down to 0. For a lot of these, at the levels that are present after we have regulated the bad ones which we have already done, the possibility that there exists some threshold, some tiny amount above which you must go before you are going to get any cancer or some other effect is still there. We will not solve that question until you have mechanistic understanding of how these compounds work and we are still a little bit away from that on a lot of these compounds.

So, unfortunately, the probability distribution goes down to 0.

Mr. JORLING. There are immense political differences in the way it is characterized, and I think that is what you have put your finger on. Because there are some fundamental questions that must be raised ultimately about those characterizations and who makes which decision and on what basis do they make it, that is why I say there is only advocacy science in rulemaking.

If I took the wing out at 0 and was representing someone who did not want regulation, I could characterize that in a way that would attempt to persuade a decision maker not to regulate as

stringently as they might if they characterized the probability at something greater than 0. So, that is where the advocacy science is used, and it is used to make a point. It is used to represent a position on an issue.

The other thing that I think you are getting at is when the curve doesn't go to 0, what is the situation as it presently stands? Then you ask the question, how much is it worth to avoid that exposure or that risk? And who makes that decision?

Right now, agencies make it. I made it. Dr. Goldstein has made it. Dr. Hendrie has made it, and we make it inconsistently. Perhaps that is the way it should be, but if you look at EPA's regulatory decisions in that situation, they range from value that are very low to very high, values of life saved, that kind of thing.

My feeling is that it is inappropriate for the agencies to make those decisions without further direction from Congress. I would like to see Congress give some range or some statement of what it believes a life is worth avoiding or the cost of a life that is worth avoiding. Because right now the agencies are doing it on a daily basis without any guidance from Congress.

Mr. WALGREN. I kind of get the impression that perhaps, except in some specific areas, we tend to take the dodge that it is just a risk, and that is what bothers me about the word risk. I guess in some ways I have a problem with the word risk when you say what you do in an agency is risk management. I would be more comfortable if you were able to say that what you were doing was harm prevention, because the word risk really implies that it may or may not happen, and that is the important question for an individual, but I am not so sure that is the important question—well, wait a minute. The word risk implies that it may or may not happen to a given entity, and that is an important question to the individual. It is a different question if the entity is the aggregate, is the whole of the population.

To say that there is a risk or to use the word risk when in fact we are dealing with a certainty that 0.2 percent of the population will be affected a certain way is the wrong word if you are thinking of the whole. It is the right word if you are thinking of the individual because he may or may not. He or she runs a risk. The population as a whole runs a certainty.

I hope something that we see risk assessment from the agencies that would, if that is the truth, if that is not a fantasized circumstance that makes those distinctions or doesn't lead us to assume that we are dealing with one or the other.

Mr. JORLING. I think what you have hit on is that most of the areas that EPA regulates in and other agencies in the health and environmental business regulate in is because the risk is to the aggregate. That is why we have a justification for public intervention at all. If it were just simply your telling a specific identifiable individual that they run the risk of, that person theoretically can make an individual choice as to whether they want to incur that risk or not.

But these are risks to an aggregate, and that is why public regulation is justified.

Mr. WALGREN. Are they risks to an aggregate or are they certainties to an aggregate, if you use the word risk to mean something that may or may not happen?

Mr. JORLING. They are risks of probabilities. That doesn't help to answer your question, especially trying to take it back to a constituent.

Mr. WALGREN. So, then you go to high probability or low probability.

Mr. JORLING. Yes. Since there are no smokers in the room for the moment, we could use that example. It is certainty that if people smoke at certain rates in a certain size population, some of them are going to get cancer.

Mr. WALGREN. So, that is a certainty. That is not a probability some will get it. It is a fact some will get it. It is only a probability that I may get it or that any individual in the group would get it.

Mr. JORLING. That is right.

Mr. WALGREN. Well, I am sorry for belaboring that. It is sort of a personal interest and I guess I can do it only because there aren't any other members here at the moment. But thank you very much for your basic presentations, that issue aside. I think they are certainly valuable to the discussion. We hope that they will be used as source material for people who will be trying to think about these areas in the longer run.

Thank you very much.

Mr. WALGREN. Our last witness, Dr. Frank Wolek is former Deputy Assistant Secretary for Science and Technology with the U.S. Department of Commerce and who, as I understand it, now is the director of research at Villanova University in the College of Commerce and Finance.

We apologize for being delayed, Dr. Wolek, and appreciate your being able to be here. Why don't you just go ahead and emphasize the points that you would like to, and we will go from there.

STATEMENT OF DR. FRANCIS W. WOLEK, FORMER DEPUTY ASSISTANT SECRETARY FOR SCIENCE AND TECHNOLOGY, U.S. DEPARTMENT OF COMMERCE; AND DIRECTOR OF RESEARCH COLLEGE OF COMMERCE AND FINANCE, VILLANOVA UNIVERSITY, VILLANOVA, PA

Dr. WOLEK. Thank you, Mr. Chairman.

If I can, I would like to ask that the full testimony be accepted for the record.

Mr. WALGREN. It certainly will be.

Dr. WOLEK. I will just briefly summarize. About how much time would you like me to look to?

Mr. WALGREN. Certainly, feel free to take 10 minutes, and a little more if you like if you need it.

Dr. WOLEK. Very good, Mr. Chairman. Thank you.

The core of my paper—or testimony—I am sounding like an academic again—is that agency science is problem-solving science. This not only relates to my own experience in the Government but also particularly to studies that I have done, for example, recently a study of exemplary achievements of a key mission agency. I have found that those exemplary achievements were work on problems.

It could have been opening up new opportunities, but instead it was helping solve problems.

Now, Government can't work on problems without working closely with the private sector, with those that have the problem and those who are also working on it. That means interaction all the way from program definition—which problems you work on, how you define the problems through the research, how you interpret the results, what steps you take and, finally, afterward, how do you extend the results, how do you tie them to other programs. The interaction has to be complete from beginning to end and worked closely.

However, Government cannot work closely with the private sector without strong involvement of public-minded policymakers who make sure that the work is done in the interests of the general public. When you are working closely with industry, one of the problems is you can get co-opted by the private sector. And there are more than enough examples of that. James Hightower's significant book, "Hard Times and Hard Tomatoes," is a very useful example of that type of co-optation.

Policymakers make sure that doesn't happen, make sure that the Government work is appropriate in function and scale relative to private abilities. Policymakers provide the travel programs, the support when the inevitable conflicts are going to arise, the rewards for cooperative achievement, the encouragement for the agency's visibility as a leader and not just a follower of the private sector, and they provide personal accountability to the Congress and, therefore, to the public. That is the basic kind of accountability that you can have.

When these three groups are working together and are balanced around a common agreed-upon agenda, then I find that the agencies make valuable contributions, rely upon in a proper way universities and firms, and that their staffs rise in the quality of output, which is the fundamental quality that we have to be concerned with, to the challenges that have been given to them.

Now, that is an easy statement. It was part of my responsibility and it is part of the other politically-appointed policymakers to a very difficult job of keeping that interaction working. But the core of our concern here is that there be that tripartheid arrangement between the scientists in the mission agencies and Federal laboratories, the policymakers who are politically-appointed and accountable to the public, and their constituencies in terms of the private sector capabilities working on the same problems.

For this balance to hold, you must have, first of all, politically appointed policymakers coordinating mission agency science which is not always the case.

There must be funds and support staffs to promote the interaction and the work of people closely together. That is also not frequently the case and in too many mission agencies, the result is, and I quote from one scientist, "Gee, it is very interesting. Somebody mentioned my work as being exemplary. All I do is publish it and it disappears in the black hole of journals." They don't have the funds. They don't have the encouragement for visibility. They don't have the policy backing when they get into problems with people outside their agencies to encourage them to do that.

There also has to be regular hearings of the type you are having here to provide that personal accountability for results, to assure the interaction, and to assure that there is the impact on the general public.

Finally, I would recommend an OTA study of the major programs where that interaction has occurred to serve as models for other mission agencies.

Now, the desirable state of tripartheid balance that I am talking about, in addition to not always occurring in existing mission agencies, has special problems when the output of mission agency science is information and laboratory services.

When you are coming out with a new chemical or you are coming out with results that imply some changes in technology or current practices in an industry or in the way universities operate, the interaction can occur quite easily. When you are coming out, however, with a compendium of information of what is known about the problem, where it occurs, data bases on current practices, particularly computerized data bases, it is not as easy to interact with people in the private sector.

The reason why it is not is because the capabilities in the private sector are smaller, scattered, and have more limited capital and are more limited in their own research staffs so they don't have the scientific peers with whom to work.

The result is that the mission agencies tend to, in my experience, try to do the job on their own rather than acting as a support and a stimulant to private sector capabilities in the services, that is, consultants, information service companies, and laboratory testing organizations. Output of that type of nature, service-related output, is inextricably wound up into applied science in mission agencies. It is increasingly becoming a part of the output of what they are working on.

The need for tripartheid balance is related to one of the questions in the agenda that you sent me. That is, "What is the role of the mission agencies and the Federal laboratories in the future?" If their current role is problem solving, what will their role be in the future?

Once again, I suggest problem solving, but the problems are changing and changing in important ways. Problems are taking on the following characteristics, for example emergencies, which arise from system dynamics. As our systems get larger and larger, more and more interactions between them and less and less involving of labor on an ongoing basis, small changes can not be seen until they are amplified into emergencies.

This is a simplified example. When you have small grain elevators and people go into them, there is a lot of human labor involved and they sense a lot of dust, the door is opened up and ventilation can be provided. When it is a very large facility and there is no human labor involved, that dust can build up until it takes the form of an explosion.

That is the type of effect that I am talking about, and it occurs in many, many areas: the avian, chicken and turkey, influenza attacks that we have had—catfish farmer where you have one particular breed and a disease that would normally be kept in bounds when you are dealing with small sizes of herds of catfish amplify

when you are dealing with one breed into an entire decimation in a very rapid form of the herds.

A second kind of problem is implementation which requires 100-percent participation, where you can't say, "OK, we have most of the people out there doing what we think should be done, that is all we have to do." That is not acceptable. Everybody has to be involved or nothing occurs, for example, the attack on the boll weevil in the Southern part of the United States. Every farmer had to be involved. Every agent of a local government agency had to follow standardized practices. There had to be cooperation in the acquisition of information and the following of the control practices. That requires education, information monitoring, standardization on a massive scale.

A third type of characteristic of future problems is when the causes stem from accumulative and hidden effects, when you can't just talk about one particular cause that is fairly visible but when it occurs over long periods of time as a result of residues built up in the environment, built up in people, built up in animals, built up in the walls and the floors of the places where we are.

It is very difficult to work on those types of problems, and the importance of interaction between the scientists and the people in the private sector are vastly greater for the three types of problems that I am talking. We set up a huge Federal facility for science. They are very, very talented people, but they are just beginning to interact with private sector capabilities on the scale that these new problems are going to require.

I am sure from what I have seen that they have the talent. I know the public looks to these Federal laboratories and admires them. I now believe they need the support and increased openness to be able to accept and meet these challenges.

Thank you very much.

[The prepared statement of Dr. Wolek follows:]

THE POLITICS OF APPLIED SCIENCE IN MISSION AGENCIES

Francis W. Wolek

Director of Research, College of Commerce and Finance

Villanova University - Villanova, Pennsylvania

Testimony before the U.S. House Committee on Science and Technology

Science Policy Task Force Hearings on

Science in the Mission Agencies and Federal Laboratories

October 24, 1985

One of the highlights of my career has been my association with the mission agencies of the federal government. As Deputy Assistant Secretary for Science and Technology with the U.S. Department of Commerce, I was privileged to work with the outstanding professionals making up the scientific staff of the National Bureau of Standards. After my return to university research on science policy, I was equally honored to do research on some of the world's leading laboratories in the dynamic field of agriculture (The U.S. Department of Agriculture's Agricultural Research Service). I come before you now, because I believe our mission agencies and federal laboratories are in a period of transition which holds both danger as well as promise for American Science Policy.

The Packard Report on the National Laboratories states that this "laboratory complex constitutes an impressive national research and development asset." The heart of the issue before the nation is the definition of the function of this asset. Why is it an asset? Whom does it serve? How does it operate in partnership with other institutions? As this Committee's "*Agenda for a Study of Government Science Policy*" points out, this longer term objective of "achieving a deeper understanding" is basic to the policy issues of organization, accountability and oversight. The theme of my contribution to your deliberations is based on the Biblical maxim that "By your deeds will you be known".

EXEMPLARY ACHIEVEMENTS: PROBLEMS AND THEIR SOLUTIONS

The core of my testimony is based on a study I recently performed of key achievements of laboratories in the Agricultural Research Service (ARS). While the data were specific to ARS, my exposure to other agencies, leads me to believe the findings are generally relevant. The ARS study was based on a sample of 47 achievements in applied science which were a source of pride in the agency and/or the community it serves (i.e., nominated cases came equally from Laboratory Directors and Directors of Research at leading trade associations). My research sought answers to how many of these cases both (1) conformed to principles on the management of applied research

abstracted from academic studies on this subject and (2) had indeed had positive impacts on agriculture practice. This testimony only concerns those 31 cases in which there was an actual and positive impact.

What type of applied science is admired for its practical benefits? You might think the answer is work which opens new opportunities not recognized before creative science uncovered them. You might think it is stunning breakthroughs in exciting disciplines such as genetic engineering. Or you might think it is the output of a brilliant individual cutting through the errors of previous practice. In each case, I was surprised to find that odds were you would be wrong! The applied science admired both within and without ARS was work which helped users (farmers, suppliers, local governments, etc.) *solve a problem* and which was the joint achievement of a *leaders from the worlds of science and practice.*

In short, successful science in mission agencies is problem solving science. Such findings should not be surprising. Experts on the mission agencies such as Henry Lambright who testified before you on October 2nd ("Missions have to do with energy, space, defense, or some other national problem") have emphasized this fact. What was surprising, however, was the magnitude of the finding. I gathered data on 47 different accomplishments, 31 checked out as yielding actual value in practice and 25 of these involved applied science (4 related strictly to technological design and 2 were projects which produced computerized data bases). Of the 25 scientific projects, 24 were directly tied to a problem of some type, usually one which took the form of damaged yields or quality (e.g., weeds choking growth, diseased output, inadequate water supplies, etc,).

Most of the projects involved quite sophisticated science. They were not simple extensions or accumulations of existing knowledge. Furthermore, in almost every case (23 of the 25 projects), a significant change was involved in accepted practice, one that meant change in the skills, staffs and procedures of practitioners. Another distinguishing feature was that government was already an active player on the problem (in five cases local government had the lead role in fighting such problems as insect

control and in another nine cases federal regulatory agencies were significantly involved). This last point bears further stress by referring to the words of Henry Lambright who noted that the mission agencies "are unique in being of the government...They are extensions of government policy" so that their involvement in the problems is a central concern for both wise policy and reasoned understanding of users.

THE POLITICAL PROCESSES OF APPLIED SCIENCE

One of the main points of my testimony is that: the success of the 25 projects stemmed directly from the *political processes* by which they were managed. If I were a social scientist I would not use the term "political". Instead, I would speak about an "integrated social structure", or "participatory networking" or the "joint action of stakeholders". Whatever words you use, the basic issue is politics in the finest sense of the word: getting people with diverse interests and capabilities to work together for common ends.

Now let's be more specific about how science is used to serve the needs of its users. In doing this, I need to refer to three principles which emerge from academic studies. Briefly stated, this literature argues that the results of scientific projects will only produce change if: (1) projects are mutually defined by scientists and the users who must implement the changes (i.e., those with the problem), (2) users directly interact with and share in the decision making during the research (i.e., people work together on-site to understand needs and operating conditions) and (3) the findings are aggressively disseminated through networks of opinion leaders in the user community (i.e., recognized people put their reputations and money on the line). My study found that there was still a significant chance of success if only two of the three principles were followed, but that is quibbling (in the 13 cases where none of the principles held, only 3 had a valuable impact). The basic point remains: government scientists must work directly with users if applied science is to have an impact.

Figure 1 summarizes the point by noting that: there will always be some type of relationship (active interaction, passive disregard, open opposition, etc.) between the three

groups involved in applied science -- Scientists, Users and Policymakers. If an agency tries emphasizing any one without reaching a balanced understanding with the other two you will find mission distortion, waste and conflict. Science without policy and problems leads to scientists competing with universities to produce papers for abstract journals. Dominance by policy leads to another condition familiar to our national labs: scientists giving lip service to an administrator while bootleging projects they and users want. Nor is the condition of user dominance any better, for the past has shown that it can lead the mission agencies to become firefighters on second-rate projects with negative side effects for the general public (re. Hard Times and Hard Tomatoes by Hightower).

To be sure, scientists will argue the importance of scientific freedom just as users will argue the pre-eminence of taxpayer control and policymakers the importance of vision and political mandate. The public is fortunate in having Congressional forums in which no one group is dominant and they jointly assure the public that they are facing their political mission of working together. For when they do, you may be confident that their strengths will emerge and the long-term public interest will be served.

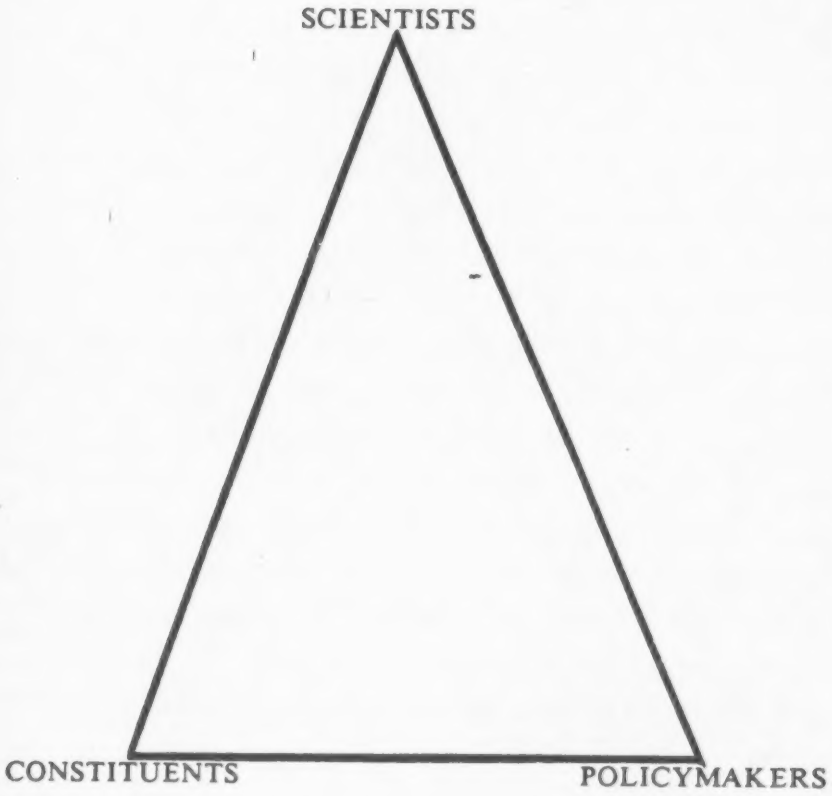
DISFUNCTIONALLY LIMITED CONSTITUENCIES-

Before discussing the implications of the above perspective, it will be useful to describe another characteristic of the exemplary projects in my studied. That is, Figure 2 describes 27 of the 31 projects according to the nature of the contribution to users who have the problem: (1) a new agent (e.g., a herbicide) which promises increased effectiveness, (2) a new test method (e.g., test for toxins in grain) which promises better diagnosis and monitoring of effectiveness and (3) new information (e.g.,a compendium of on the occurrence and control of a farm animal disease) to guide users in avoiding or controlling the problem.

Recall that a critical factor in the success of applied science is strong interaction with an active constituency from the start of a project through its early implementation. When new agents (insecticides, vaccines, plant varieties, etc.) are the outcome, the nature of the constituencies is clear: both producers who are experiencing the losses and

Figure 1

THE SUPPORT STRUCTURE OF FEDERAL LABORATORIES



industrial suppliers who market such agents (chemical firms, drug companies, hybrid seed producers, etc.). What is also clear is the process of interaction: working through a farm organization to produce grass-roots participation and with peers in R&D at the suppliers.

The situation is quite different with the other kinds of contribution: consultants and testing organizations are loosely organized, widely scattered and lacking in the R&D staffs permitting peer relationships. In short, current practice works well when the output of applied science promises a new or better product. When the output promises a new or better service, the system often breaks down.

Working with consultants, testing labs and information companies is indeed more difficult and less rewarding (e.g., because they are small, the same message has to be repeated many times, because they are more narrowly focused the message must be adapted to be heard, because they lack discretionary capital they resist staff and equipment innovations, etc). However, as long as mission agencies produce service-enhancing results (and these are inextricably involved in the problems of users) and as long as the Congress and the Office of Management and Budget will not accept mission agencies becoming commercial service operations (which would be wasteful competition with growing, private sector capabilities), we have no choice but to find ways to aid and encourage the mission agencies to work with private-sector service firms.

My message is simple: the problems of users are driving mission agency professionals into a corner. They can't help but generate service enhancing results, but they lack the internal and external support for the more difficult tasks of working with service firms. Therefore, they either publish the results and fret that no one responds or they offer limited services themselves ("we'll just do it this once to show it can be done", or "we will only help our local friends", or "we'll start our own "extension" service") and fret about inadequate budgets and misdirected talents.

A Congressional Hearing on the *Mission Agencies and the Service Sector* would serve a national need by bringing this growing problem to the attention of all concerned and yielding such practical benefits as:

- o defining the criteria for determining when mission agencies are in unwarranted competition with private organizations and when they stimulate that sector's growth;
- o highlighting the function of specialized training, field days, private sabbaticals and other ways of generating interaction between private experts in the services and government scientists;
- o providing a stimulus for private services to become better organized for working with mission agencies,
- o pin-pointing specific situations where public resources could be saved by terminating duplicate services between private and government organizations,
- o sharing lessons between agencies on successes such as the Patent Office's sale of its full-text data-base and the Environmental Protection Agencies conferences for computer firms on water-management models).

REPLIES TO INQUIRIES IN THE AGENDA REPORT

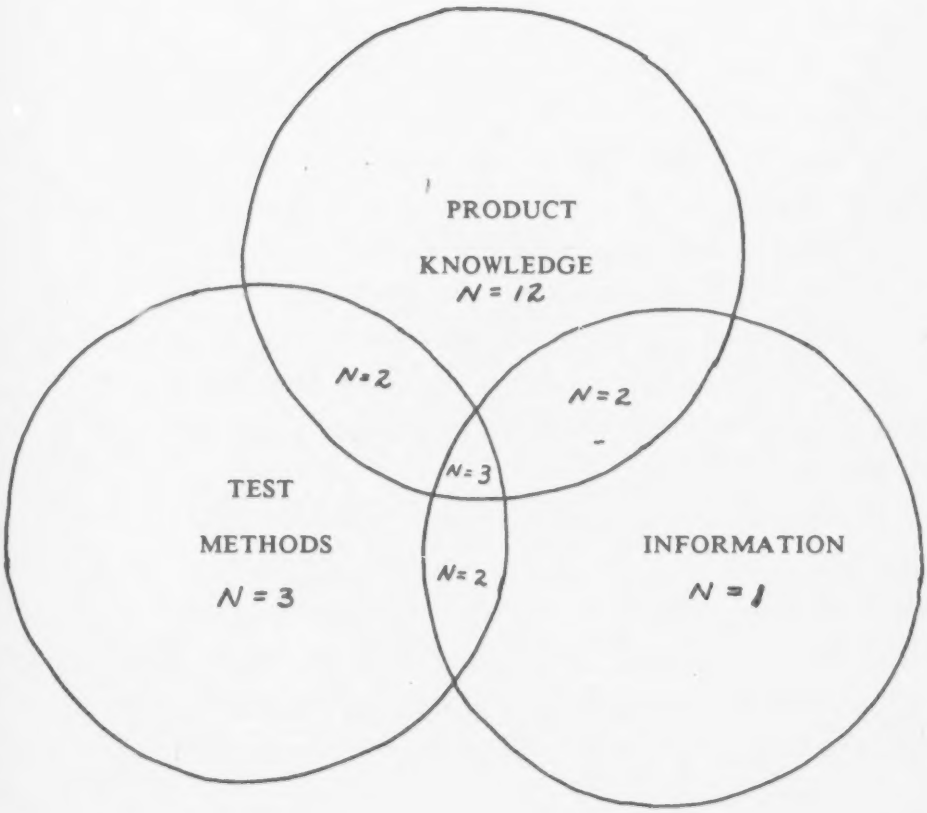
The Committee has been generous to its witnesses in providing the "*Agenda for a Study of Government Science Policy*" with its specific lists of questions to which you wish answers. Therefore, I will restrict my discussions of the implications of my remarks to those issues.

What are the Present and Future Roles of the Large Number of Government Laboratories?

The data obtained are consistent with the testimony of other experts on the role of federal laboratories and mission agencies: they are the base of scientific expertise for contributions to the solution of problems of wide concern in society and in which public policy plays a role. The specific contributions of the laboratories are :

Figure 2

THE CONTRIBUTIONS OF FEDERAL LABORATORIES



- o knowledge which defines the potential of and/or improvements in practices and technologies which would alleviate the problem,
- o information services which instruct users about the extent of the problem and actions they may take to minimize it, and
- o technical services which assist private sector organizations to better understand the problem.

The laboratories have an excellent record as producers of useful knowledge when there is time for published information to be useful and where there is a consensus that government possesses unique capabilities. Such work will undoubtedly continue to be of importance as new problems emerge. However, as other witnesses in these hearings have suggested, both of these conditions are increasingly less likely to hold. In particular, the laboratories and their mission agencies will need to adjust to needs for direct interactions with increasingly strong and diverse talents in universities and private organizations. To combat this situation, the mission agencies will have to greatly increase their capacities for working in cooperation with other scientific groups and with the networks of suppliers, practitioners and associations (e.g., enhanced travel budgets, readiness of policymakers to handle conflicts, recruitment and promotion practices which recognizes cooperative accomplishment, increased ways of being visible as a catalyst of scientific consensus, openness to project re-orientation based on outside consensus, etc.).

My studies also suggest that the mission agencies have had special problems making information and service contributions in ways which recognize the capacities of information companies, technical service laboratories and consultants. While there is sufficient reason to strengthen these abilities in terms of today's challenges, the need is even greater for the problems which mission agencies will face in the future. For example:

- o *Problems Traceable to System Dynamics* - as our systems become larger, more and more tightly inter-related and less dependent on human labor, errors in one element of the system can be multiplied into suddenly appearing emergencies (e.g., grain elevator explosions, chicken influenza epidemics, catfish farming disease catastrophes);
- o *Requirements for 100% Participation* - there are many problems where the solution is dependent on all practitioners following a prescribed course of action, therefore, education, testing, consulting and monitoring services are crucial (e.g., where exports of cherries to Japan depend on all packers conforming to insect control practices, where the elimination of the boll weevil requires 100% coverage of farms and coordinated practices across all local agencies, where control of disease requires 100% testing of flocks and 100% destruction of exposed animals); and
- o *Problems Traceable to Accumulative, Hidden Effects* - increasing sophistication in health and environmental sciences shows that many problems arise not from any one cause, but from slow and often hidden accumulations of the interactions of multiple factors and the result is a need for sophisticated testing, on-line data-bases and education on seemingly innocuous practices (e.g., waste handling, long-term effects of farm chemicals, interactions of nutrition and environment on human health).

What Should Be the Policy with Respect to the Establishment of New National Laboratories and the Reorientation of Existing Facilities?

There are three indispensable groups which are needed for a productive contribution by federal laboratories: scientists, policymakers and (most important) users. This structure gives rise to the following rules regarding the establishment, termination and reorientation of laboratories:

- o If the actions of all three groups fail to support the lab, do not establish a new lab or terminate an existing one with appropriate policies on relocation and adjustment of the staff.
- o If the actions of any two groups fail to support the lab, a new one should not be established (i.e., science or policy should not "push" a productive lab into life) and an existing one should be placed on short-term trial with the specific mission of reorienting to obtain the needed support without loosing the existing.
- o If the actions of two groups show balanced support, but the action of any one group fails to support the lab, and if
  - the missing group is the most critical one of private sector users, the lab needs reorientation on the problems which it is addressing and its programs for cooperating with the private sector;
  - the missing group is that of policymakers and the Congress believes the lab is serving a vital function, the Congress should call on the Executive for accountability and/or serve as interim policy support;
  - the missing group is the scientific staff (i.e., it has lost vitality or currency), the lab may be reoriented via the introduction of a critical mass of new scientists.

The primary means which may be used to assess the health of each group's support and to structure the reorientation when needed are:

- o *Constituents* - Advisors convened in "Strategic Conferences" which meet every 3-5 years to define program directions and cooperative goals.
- o *Policymakers* - Congressional Hearings centered on politically appointed policymakers who are personally accountable for mission agency effectiveness and impact on the general public.
- o *Scientists* - National Academy and other scientific advisory groups.

How are Decisions Made with Respect to the Science Programs to be Done in the Government's Own Laboratories versus Their Conduct Through Grants and Contracts?

It is commonplace to note that there is no simple answer other than it depends on the circumstances. Figure 3 presents a framework which provides a useful perspective on these differing circumstances. In each of these situations, private sector research groups interact in some way with the same parties as mission agencies. When the interaction is only between scientific peers, the basis for allocation between agency and private laboratories will be peer evaluations of scientific interests and capabilities (judged by publication record, laboratory capabilities, theoretical focus of work, adequacy of methodology, etc.). The second situation occurs when government and private groups do not directly interact, but both have related contacts with practitioners. In this situation, the judgment, temporal needs and practical exigencies of the practitioners will have much to do with how funds are allocated. When no interactions with common communities is present, administrators must make allocations based on their understanding of political pressures from their own labs, Congress and constituent lobbies. Obviously, it is best to avoid this third case, and the best situation is described by the fourth where there is a consensus including both outside peers and practitioners.

What is the Record of the National Laboratories in Attracting and Retaining Highly Qualified Research Personnel?

My reply to this important issue is: whenever the users of an agency actively interact with its policymakers and share a consensus on the mission and agenda of the agency, then the scientists will rise to the challenges implied in that consensus! In other words, I have great respect for the scientists I have worked with and studied at mission agencies. They may not all have Ph.D.'s from our elite universities, but given an important and valid challenge, they perform.

This upbeat note which reflects my deep respect and admiration for the dedication and competence of the mission agencies is an appropriate end to my testimony. Thank you for the honor of appearing here.

A Case Study in Civilian Technology

Francis W. Wolek

ABSTRACT. This case study documents the difficulty of initiating civilian technology programs in government. Earlier work has focused on the political actions of supporting and opposing constituencies. This paper deals with institutional factors in the process of resource allocation, which are designed to create obstacles to the initiation of new programs. The paper also outlines managerial tactics available to government executives, which may mitigate the obstacles when coupled with responsible analysis of public needs and values. It concludes that civilian technology programs are difficult but feasible undertakings and that, despite their scanty record of success, they can be deserving of public resources and support.

The public's confidence that modern technology is a cornucopia of jobs and economic progress has motivated politicians to support programs promising enhanced innovation, those of the so-called Atari Democrats being only the latest in a long line of clarion calls to participate in the bright tomorrow of a technological society. These initiatives have won important support—transcending the Manichean world of politics—from academics who share the public's confidence in technological progress and who also wish to enhance the contributions of universities to society. No less than a Nobel Prize-winning economist has provided the theory needed to argue an indispensable role for government. Briefly, Kenneth Arrow argues that private aversion to risk and inability to appropriate the full benefits from innovation will lead industry to underinvest in long-term, far-reaching R&D.

Given the political power of public confidence and support of leading people, the concept of civilian technology has been accepted by most modern administrations of the US Government (*e.g.*, the Civilian Industrial Technology Program of President Kennedy; the National Technological Opportunities Program of President Nixon; and the Innovation Initiative of President Carter). Despite the attractiveness of the concept, and despite the strong support of Republicans and Democrats, the record of accomplishment for civilian technology programs is modest at best (see Katz for a fine review of the history of major programs).

Francis W. Wolek, currently at the College of Commerce and Finance of Villanova University, has spent most of his career in academic research on science and technology policy. He has also had the opportunity to implement his own and others' scholarship as Deputy Assistant Secretary for Science and Technology at the US Department of Commerce and as Vice-Chairman of the US Guayule Commission.

The coupling of great promise with apparent failure has attracted the attention of all concerned: scholars (*e.g.*, Magill and Rogers), government officials (*e.g.*, Schlie), and industrialists (*e.g.*, Baer *et al.*), alike. The conclusions of much of this previous work appear to be that either civilian technology is an improper goal of government (*e.g.*, the work of Eads and many industrialists) or that executives of superordinate talent in politics as well as technology are needed for success (*e.g.*, the work of Nelkin). In each case, the message of policy analysts is a negative one, discouraging further efforts to create and/or manage civilian technology programs.

It can be assumed that technology will continue to be a major focus for public confidence (*i.e.*, civilian technology programs will continue to be a favorite of politicians) and that the government officials placed in charge of these programs will possess quite ordinary talents. In short, the dangers of future failure are high. To combat these dangers, the author will offer several lessons learned by a student of technology policy who was privileged to apply his—quite ordinary—skills to the management of a civilian technology program to create a domestic, natural-rubber industry.

Perspectives on Government Programs

The lessons offered here stem from an "institutional" perspective which views the management of government programs as a process of simultaneously addressing the requirements of interest groups outside government, bureaucratic procedure, and executive policy. In adopting this perspective, this discussion is closer to the work of such scholars as Cyert and March than to the perspective of the social/political school, such as Nelkin (the political perspective) or to the work of economists of technology policy, such as Nelson, Peck and Kalachek (the rational perspective).

According to the political perspective, the success of government programs is largely a function of the political power of friends and enemies. Key questions concern the strength and skill of supporting officials and the influence of external constituencies. From this perspective, a successful program would be one which was supported by the President and Congress, and managed by officials who understood political power and made sure it met the needs of an active constituency.

The rational perspective places its emphasis upon the justification of a program. Key questions concern economic returns to society and to those in industry who will be needed to commercialize the technology. A further question, especially targeted to government programs, is why private groups, acting on their own, cannot obtain the returns indicated (*i.e.*, why is the government needed at all?). From this perspective, a successful program would be one which provided high value to both the public and industrial producers who would otherwise have to settle for less.

The political and rational views have dominated most of the literature on civilian technology programs. From these perspectives, the failure of the programs must be traced to errors in either the design of the programs or in the use of power in managing them. These are valuable lessons; however, it appears that they oversimplify the requirements for program success. For example, important, recent work (*e.g.*, Bodde) has stressed the need to understand the decision processes of government, and to integrate political and rational analyses of programs. Political power and

economic return are necessary, but they alone are insufficient for the success of civilian technology programs.

An additional perspective is necessary, one concerned with the internal workings of the government itself, *i.e.*, the institutional perspective. The key questions seen from this perspective are: the support of interest groups in the government, ability to meet bureaucracy on its terms, and skill in maneuvering around policies which can facilitate or retard a program. From the standpoint of this perspective, the successful program will be one which fits the interests of multiple parties in government, has the enthusiastic support of people who understand government procedure, and is positioned to fit the formal policies of executive agencies.

The Program

Rationale and Program Description

Guayule is the common name for a bush (Parthenium argentatum) which grows naturally in the deserts of the southwestern United States and northern Mexico. Public interest in guayule is based on its production of high-quality latex, similar to that produced by Hevea trees growing in Malaysia and South America. Natural rubber is important to public policy, because it has significant military uses (*e.g.*, tank treads), and because the United States is militarily dependent upon imported rubber. Additional public benefits concern guayule's potential contribution to the economic development of arid areas.

The guayule program was brought into existence on November 4, 1978, by the Native Latex Commercialization and Development Act (P.L. 95-592), which authorized $30 million for R&D and commercialization over a three-year period. The result envisioned was a vigorous industry which would grow guayule bush and process the latex into high-quality, natural rubber. P.L. 95-592 also established a United States Guayule Commission made up of representatives from the Departments of Agriculture and Commerce (three members from each), and the Department of the Interior and the National Science Foundation.

History

Guayule production was supported by the US Government in the 1940s when the Japanese takeover of rubber plantations in Malaysia highlighted the strategic significance of natural rubber. The needed seeds for some 5,000 acres of guayule in the southwestern states were obtained from uncontrolled collections of wild bush in Mexico.

Confirming the cynicism of those who believe that government is fickle, the program ended with the war, and the guayule was burned as it stood in the fields. This abrupt termination—which left no time for records of the scientific work—and its lesson of the temporality of political support would continue to haunt supporters of the modern program.

The plight of the semi-arid lands of the Southwest in the 1970s (rapidly declining water tables, economic hardship for farmers of irrigated land, and threatening

dust-bowl conditions) generated renewed interest in a guayule industry. Predictably, interest led to the formation of a "blue ribbon" study group, and a National Academy of Science panel examined the scientific, technological and economic feasibility of developing a native latex industry in the United States. The findings of this study were that an industry was feasible, but that it would require substantial effort in: (1) plant breeding for higher rubber content; (2) development of successful agronomic methods; (3) development of profitable processing technologies; and (4) support for an agricultural and industrial infrastructure.

Congress, however, would not tolerate a long (15-to-25-year) plant breeding program; they saw the program as ready for active promotion. Therefore, Congress divided responsibility for guayule development between the Departments of Agriculture and Commerce. The Agriculture Department would be responsible for accelerated research on plant breeding, and also the development of agronomic practices, while the Commerce Department would be responsible for research on processing technology. Both departments would share responsibility for the development of an industrial infrastructure of farmers and processors.

Political Context

There was important support for the Guayule Program from farm groups in the southwestern states, based upon the prospect of establishing a new cash crop. The need was based on declining water tables resulting from heavy irrigation of the most widely produced crop: cotton. If forecasts of further declines proved true, farmers would be forced out of cotton production, and either into a new crop or out of business. This resulted in Congressional interest in and pressure behind the program. Since the threat was in the future and there were no existing guayule farmers, however, there was no strong constituency behind the program. In this regard, the guayule program is an excellent prototype of most civilian technology programs.

It is important to note that there was also clear interest on the part of some farsighted rubber companies, who perceived a day when they might need alternate supplies of latex. Goodyear and Firestone were especially active, and the latter maintained a small guayule plantation. Finally, it should be noted that, for several years prior to the Native Latex Act, the National Science Foundation (NSF) supported academic research on guayule. The result of NSF's work was a significant group of university scientists experienced in and committed to native latex research.

Institutional Obstacles to New Programs

One of the most basic tasks facing all supporters of a civilian technology program is to obtain the necessary funding. To the public, commerce and industry, the amount of resources expended on a program is a fundamental measure of both the commitment of the government and of its success in backing that commitment with action.

The Native Latex Act of 1978 authorized the expenditure of $30 million in federal funds for a period of three years. In response, groups in the Southwest (mostly universities and potential farmers) turned to the Commerce and Agriculture Departments for funding. Actually, over the first three years of the program, the Agri-

culture Department provided approximately $3 million in funds, and the Commerce Department provided approximately $200,000. The contrast between expectations and actual funds was frustrating to political supporters and to advocates hoping to enter the natural rubber business.

Authorization vs. Appropriation

Most people outside government believe that, when the Congress passes an act which authorizes funds, these funds are immediately available for use. This simple view of government funding is simply invalid.

Funds must be "appropriated" to match an authorization, and program staffs must be recruited and organized. Appropriation is a different process from passing authorizing legislation, and generally requires that the Executive Branch request funds and that these be approved by departmentally organized Appropriation Committees in Congress. Since the Guayule Act was not initiated by executive agencies, and was not expected, no prior work had been done which would lead to the early availability of funds. The earliest that funds could possibly be available would be October 1979, if the Commission could include Guayule in the 1980 budget.

The Dynamics of the Budget Cycle

When the act was unexpectedly passed in 1978, the agencies involved had completed preparation of their 1980 budgets (Fiscal Year 1979 had started in October 1978). Budget requests, not including Guayule funds, had already been developed and processed by the Office of Management and Budget (OMB). The "budget window" had closed, and funds for Guayule had to wait for the 1981 requests. The importance of timing in the "budget cycle" is generally not understood by the public, but is a fact of life in the bureaucracies that are as much its victim as its master.

By the time the Guayule Commission had met and approved a clear strategy, six months later, the 1981 budgets were well on the way to development. There were programs, however, already in the 1981 budget which were in existence prior to the Native Latex Act. Therefore, the Guayule Program had to compete with an already structured budget, backed by prior commitments.

Agency budgets are not open-ended, and—for almost all intents and purposes—are best thought of as fixed. In other words, the budget process is a zero-sum game, and new programs are only possible if existing ones are cut. Needless to say, it is always difficult for a new program to cut into an established budget, either in terms of a large request or a high priority. Indeed, it was not until the 1982 Budget request (which won OMB approval in the fall of 1980) that significant new funds would appear in the President's Budget.

Program Authority and the Lead Agency Issue

One of the more important policies which guide the budget process is that an agency cannot receive appropriations unless it has both the legislative authority and OMB (*i.e.*, White House) approval to commit such appropriations. Authorities to

make grants, guarantee loans, support market prices, and enter into construction contracts are not possessed by all agencies. If the agency charged with managing a civilian technology program lacks the needed authority, it must either obtain it—a time-consuming and politically sensitive process—or it must convince a sister agency, facing its own priorities and political pressures, to cooperate in the program.

The function of program authority in the budget process should be clear. By limiting the number of agencies with authority to make specific types of resource commitments, budget officials simplify the budget process and make sure that resources are concentrated in agencies with the needed mandate and expertise.

The issue of program authority is raised to an even higher level of importance by the "Lead Agency" policy of OMB. According to this policy, a specific agency of government is designated as the only one which may commit resources directed toward a specific mission of the government. For example, the Environmental Protection Agency is the lead agency on funds for research on environmental pollution. All other programs needing resources for pollution research face the difficult task of convincing EPA to replace its own requests with theirs.

The Agriculture Department was successful in including funds for Guayule in its budget for agricultural research, since the USDA was already the lead agency in charge of that mission. An added helpful feature was that guayule research would require a small budget relative to USDA's total program for research at state land-grant universities. Therefore, substantial shifts in the agricultural research program were not necessary to accommodate Guayule proposals.

The Commerce agency in charge of the Guayule Program was operating without an established program for making research grants, and faced the difficulty of winning new program authority. Needless to say, the whole concept and function of the lead agency policy would be a sham if it were granted easily and for such narrowly specific missions as native-latex industrial development.

In summary, OMB argued that, if the Guayule Program were important, it should rank high in efforts to utilize existing funds rather than make a claim on new funds. The difficulty with this argument was that there was an already established constituency defending the existing pattern of funding.

The Necessity of Avoiding Reprogramming

Obviously program funds are more easily obtained if the agencies involved are the lead agencies for the needed tasks. The question arises as to why the Commerce representative on the Guayule Program was not from an agency with relevant authority.

There are two answers to this question of representation, and each of them has important implications for civilian technology programs. The first concerns the fact that there was a Commerce agency with lead agency authority to make large grants in the interests of regional economic development, *i.e.*, the Economic Development Administration (EDA). Once the Native Latex Bill was made law, however, EDA officials carefully avoided involvement with the program. They took such action to avoid pressure to "reprogram" (to substitute new projects and priorities for existing ones). EDA's program was a complex result of lobbying from powerful

groups which had long experience with the agency (*e.g.*, state and local government, industrial associations, and unions). If an official could avoid trading off one group or Congressman against another by sidestepping membership on a new "Commission," it was certainly worth it.

Another agency, one which supported research on industrial technologies, was the National Bureau of Standards (NBS). Again, if Guayule officials had ordered a program of research at NBS, and they had the formal authority to do so, existing programs (which those same officials had fought hard to defend) would have to be cut. In short, the necessary informal authority did not exist. Indeed, it was not surprising that NBS scientists, fearful that the formal authority might be used, resorted to the career official's arsenal of procedural, scientific and political steps to avoid reprogramming (see Heclo for further, fascinating details).

Barriers to Multidimensional Authority

The second factor affecting the use of lead agency authority concerns the type of authority available versus the type needed to carry out the mission. The Guayule Program involved a combination of R&D and industrial planning, while agencies tend to have very specific authorities.

Problems of matching civilian technology needs and program authority/experience will undoubtedly continue to plague such programs. It is their special nature to combine significant advances in technological state-of-the-art and infrastructure development. Such combinations of program authority and expertise are rare. The problem can be dealt with by creative work between existing agencies. This, however, takes considerable time, commitment, and the good will of other agencies.

Presidential and OMB Priorities

In the case of Guayule Program, the author (as Vice Chairman of the Commission) made matters worse. The President had made a speech, and negotiated a treaty with Mexico which gave support to cooperation on desert plants, including Guayule. It seemed that, if the Guayule Program could be included in the Department of Commerce request to OMB, its priority did not matter. In other words, it seemed that Presidential interest would overcome the usual need to compete with established interests.

Nothing could have been as wrong and as naive as the assumption that OMB would automatically support a Presidentially backed treaty. In fact, the President's speech and the treaty had little influence on the budget process. Presidential commitments have validity, to be sure, but are a political expression responding to domestic and international forces. Program officials still hold responsibility for guiding budget requests past the necessary challenges of Departmental, OMB and Congressional watchdogs.

Summary

New programs come into existence as a result of lobbying by individuals with the vision and self-interest to define them. The nature of Congressional processes in

the US, (typified by officials who must be sensitive to local interests, relatively short leadtimes, and specific points in time when pressure will be effective) make it possible to pass enabling laws which authorize funds. Lobbying groups, however, must begin again, if they are to translate success in authorization into the reality of program funds and staff. This second process, often not understood and appreciated, is centered on the Office of Management and Budget and the Congressional Appropriation Committees. It is a far more difficult and time-consuming process.

The Office of Management and Budget is an effective watchdog for public funds. OMB has an extensive arsenal to protect the public against untimely or purely political programs. This arsenal includes: (1) policies (*e.g.*, the lead agency policy); (2) procedures (*e.g.*, the inter-program competition for priorities needed in zero-base budgeting); (3) bureaucracy (*e.g.*, the long lead-time involved in budget preparation and approval); and (4) informal means (*e.g.*, career executive defense of the *status quo*).

Civilian technology programs find the above obstacles especially imposing, because the programs are: (1) new in concept; (2) lacking in large, established constituencies (by definition, they are in areas in which private groups have not acted); (3) dependent upon politically appointed and bureaucratically inexperienced officials; and (4) difficult to document with data on cost effectiveness (by definition, the technology has not yet been developed).

In short, from the standpoint of theory, civilian technology programs are promising and exciting. The Guayule Program shows that they are also feasible. This feasibility, however, is only possible given time, persistence and luck!

The Role of Program Management

All of the above (budget-cycle timing, lack of lead agency authority, and reprogramming avoidance) are aspects of the institutional structure of the federal government, which lengthens the time and increases the political strength required for civilian technology programs to be established. In terms of the overall public good in avoiding proliferation of weak programs, this situation is undoubtedly to the good. For those committed to civilian technology programs, however, it is very frustrating!

Fortunately, there are options open to officials who are willing to accept the institutional structure and experienced enough to recognize the considerable stock of managerial tools available to them. The managerial approach will probably never deliver the funding and the scope of activity needed for full-scale implementation. However, this approach will preserve program momentum, and succeed in making basic contributions of data and network organization.

The four elements of this managerial approach, which played a strong role in the Guayule Program, are:

- Officials of agencies with appropriate program authority were cajolled into using their funding to support the Guayule Program;
- Interim funds were begged and borrowed to maintain program momentum and provide basic knowledge for future planning;

- New program authorities were piggybacked on more politically attractive programs; and
- The program was redesigned to fit available funding.

The Politics of Mission Identification

In attempting to win the support of officials in government, much depends upon whether the new program is seen as compatible with an agency's mission and supportive of its stature with the public. The top officials of the US government are politically appointed and, therefore, always attentive to public favor.

When the Guayule Program was originally conceived, it was identified as a program for the "Utilization of Arid Resources." This identification was neatly related to the public interest in resource conservation. By the time the act was passed, however, the concept of conserving the earth's resources was no longer politically significant. Equally important, the mission of conserving arid resources had only narrow relevance (*i.e.*, agricultural research) to the two departments which were to play primary roles in the program.

A mission which was both more relevant to the bureaucracy and more politically meaningful was the concept of "Rural Development." This concept of economic development for rural areas was especially important in justifying a wider scope for USDA's support than that of agricultural research. If the Guayule Program had been successful technologically, there would have been a need to provide loans and subsidies to farmers who would experience no cash sales until their plants matured. Such funding was only available for the mission of regional economic development.

The definition of mission for the Guayule Program was not static, and had to change repeatedly to keep pace with a dynamic political climate. For example, later in the program's history, it became prudent to emphasize the program's ties to "National Security." The United States had a minimal stockpile of natural rubber available, and the Defense Department had listed natural rubber as one of its top three materials in short supply. This concept of critical materials was very important in efforts to justify funding via the Defense Preparedness Act implemented by the Office of Emergency Preparedness.

In summary, civilian technology officials must be attuned to politically viable concepts in their dealings with the public and other officials. In addition, program missions are important in winning the personal commitment of officials in charge. If a program does not support the overall philosophy and personal ties that motivate a key official, it will get nowhere.

Extra-Budgetary Hustle

The officials on the Guayule Commission found that, if they were to obtain any funds for the Guayule Program (before the hoped-for 1981 Budget), it was necessary to find sources of interim funds that were both appropriated and uncommitted. The task was to convince the officials in charge that guayule was a valuable and relevant way to use their funds.

The Commerce Department was successful in obtaining a decision to allocate

$100,000 from the Secretary's discretionary fund. The funds were used for a study on the by-products (resins, waxes, etc.) produced in guayule processing. This research was important, because the economics of guayule processing could depend upon the value of the by-products obtained. Neither the market values or the costs and difficulties of obtaining these by-products was adequately understood.

In the Agriculture Department, extra-budgetary hustle was successful in generating $500,000 from the Energy Department (DOE) by using personal friendships and the argument that natural rubber would conserve petroleum used in producing synthetic rubber. These funds played a role in the efforts of Agriculture to obtain a sufficient supply of seed of the highest yielding varieties. Without adequate seed, it would be impossible to plant the large plots needed to test and to develop agronomic practices.

Piggybacking Program Authority

As noted above, there was no chance that Commerce could establish program authority for as small and as politically weak a program as Guayule. The Guayule Program, however, could be packaged as one application of the broader mission of industry-government cooperation in technology, and this concept did have broad public support, particularly on the issue of technological competition with Japan. In addition, there were other "orphaned" technology programs which lacked sufficient authority and political power. Finally, Commerce's Guayule officials were no longer "greenhorns" with little informal authority. For example, when it came time to provide a critical priority for Guayule in the Department's budget, the Assistant Secretary in charge told the Vice Chairman: "You've given your all to support our projects; now it's your turn." In short, the time was ripe to piggyback the Guayule Program onto the general mission of civilian technology.

The result of this piggyback approach to program funding was a successful request in President Carter's 1982 budget (scheduled for initial expenditures in October 1981). The Guayule Program was made part of a new Resource Technology Program, made up of the Guayule Program and a Resource Recovery Program. The Resource Recovery Program (waste recycling technology) was also a product of legislation to promote civilian technology, and had run into exactly the same difficulties of lead agency authority and competition with established programs. Thus, two resource technology interests shared a piggyback position on an election-year issue of supply-side, innovation-oriented, industrial policy (President Carter's Innovation Initiative, which led to the National Innovation Act of 1980).

Program Redesign: The Chicken or the Egg Problem

One of the key tools of program managers is that of program design, since they are the ones who ultimately determine what will be done, and when, and by whom. One way in which this power may be used is to redesign program tasks and priorities to fit available funding. During the early stages of a program, redesign is difficult. Officials are heavily involved in the budgetary process, are learning the ropes and the program, and have no staffs to help until funds are appropriated. The result is that plans and budgets are all too easily formulated with incomplete understanding.

The key place where redesign played a part in the Guayule Program was, not surprisingly, the most expensive task of all: the funding of a factory to process guayule bush into latex. The need for government support in this area (entrusted by the law to the Commerce Department) is related to the fact that Guayule latex is entrapped in the cells of the bush and must be extracted by grinding. An added complication is that, once the bush is harvested, reactions take place which chemically link the latex with resins and other compounds in the cell walls. Separation processes for the resinated latex are highly uncertain, and were expected to require much in the way of initial R&D and pilot plant experimentation.

Before privately financed factories could reasonably be expected to be built, a pilot plant was needed to develop and demonstrate an economically feasible technology. The problem was that the economic operation of a pilot plant required high levels of capacity utilization. Thus we have a classic problem: The bush would only be grown if a pilot plant were available, and the pilot plant would only be available if sufficient bush were grown.

The Commission was handed a clear strategy for the processing problem when it came into existence. The enabling legislation for the program took the easiest approach to government support: Spend the problem away. The Commerce Department was to subsidize the design and construction of a pilot plant. The pilot plant would then enter operation until the economic feasibility of guayule had been proved, and industry would have the knowledge and incentive for full-scale commercialization.

A small problem with the subsidy strategy was that it was impossible to obtain the funds.

The Defense Department, impatient for the development of a domestic rubber industry, argued that it would be possible to stimulate private industry to fund the pilot plant. To accomplish this, the government should provide a guaranteed price —not only to farmers for bush, but also to processors for rubber. The government would purchase the rubber at the subsidized price until the venture became commercially feasible on its own, at which time the government price would be set at market rates.

The critical assumption underlying the price stimulation strategy was that the price could be set at a reasonable level. The Guayule Commission strongly felt that a reasonable price was not likely, because it would have to be adjusted for the high risks involved. The risks associated with pilot plant operation, and particularly with sufficient bush being grown within a reasonable length of time were so great that the Commission and the industry believed that the price level would have to be unreasonably high. The Commission was also concerned that the price support and subsidization strategies could: (1) encourage unscrupulous operators more interested in large subsidies than commercial ventures; and (2) require a new bureaucracy to administer the program.

As experience grew, new approaches which promised reduced funding requirements came to light. Processing uncertainties centered on the critical step of deresination: separating the by-product resins from the latex. If the bush could be locally crushed and the latex extracted in unresinated form, reliable and inexpensive technologies could be used. Indeed, it would be feasible to set a price on the unresinated rubber, given the low uncertainties and costs of a crushing/extraction operation.

The key question in this strategy is the utilization of unresinated rubber. The problem is that the longer the resins stay in contact with the latex molecule, the more they become chemically attached to it. If the unresinated rubber could be shipped within a reasonable time, however, to a centralized deresination facility (such as an existing chemical plant), it might be possible to keep the costs reasonable. The questions requiring responses are: (1) the technical feasibility of short-duration storage; and (2) the availability of deresination facilities at existing chemical plants. These two issues are easily subject to investigation and, if resolved favorably, could lead to a different and much less costly approach to stimulating the development of the guayule industry.

The Power of the Electorate

All of the above thinking and maneuvering bore fruit in a 1982 Budget request which passed review at both departmental and White House (OMB) levels. The stage was set, and real progress could begin!

Unfortunately, President Carter lost the election, and the new administration moved for large budget cuts. The proposed budget for all of the Innovation Initiative (not just the Resource Technology Program) was set at zero.

Conclusions

The above review of the Guayule Program highlights several points which may be of value to the study and execution of other programs of the federal government:

- Programs of the federal government are dependent upon personalities. It is necessary to have people who believe in a program and who are willing to commit their personal energies and reputations to its success. Without such personal commitment, a program will be ground into dust by administrivia.
- Personal commitment of officials is more likely if officials obtain the attention and support of the public and industry as they did in the Guayule Program. The effectiveness of this support requires better understanding of the budget process and the public's role in it.
- The easy way to promote progress on a government program is to spend money. Pressure for rapid funding, however, is likely to encourage unscrupulous operators as well as provide incorrect direction for federal efforts. There are frequently better alternatives than funding. These alternatives, however, take time to perceive, plan, and carry out.
- A follower of the rational approach to program management will be tempted to believe that OMB will be interested in the technology and industrial economics of the program, and that the budget process is one of rational argument. Experience in the Guayule Program teaches that anyone who believes they can outsmart or outargue OMB is on a sad road to disillusion. To do its job properly, the OMB staff develops high talents as a group of professional skeptics.
- The follower of the political school of program management may be tempted

in a different direction, that of building political support for the program, and strengthening the abilities of constituents to lobby in its behalf. This approach is both political suicide and illegal. An officer of an administration may not lobby against that administration. You may quit, if you find official policy significantly repugnant. To the public, however, you must always appear in the role of the "good soldier."

Civilian technology programs *can* work. Many of them, such as Guayule and Resource Recovery, can contribute greatly to the nation's security and economic development, and can build the type of public/industry/government cooperation which is increasingly needed in a rapidly changing and competitive world.

The Business of Technology:

A Board Guide to Profits and Progress

by

Francis W. Wolek

Directors & Boards, Volume 9 (No. 4), 1985, pp. 29-46.

SUMMARY

Technology is increasingly becoming a topic for consideration by corporate Boards of Directors as the costs of its development increase and the competitive impact of success and failure grows. This paper uses a survey of the history of technology (aircraft, steel, auto, etc.) to provide guidelines for Board members on the critical role of business judgment and vision in decisions affecting technological innovation. It especially focuses on the: (1) importance of convergences in technological and market forces, (2) the crucial role of managed learning by deploying technologies in early operations, (3) rules of thumb to estimate the costs and risks of R&D, and (4) the need to avoid greed and promote multi-firm prosperity from successful innovations.

Special Report

The Business of Technology

Part I: A Board Guide to Progress and Profits

by Francis W. Wolek

"America's High-Tech Crisis"; "A Bloodbath in Chips"; "A Technology that Could Remake Big Steel"; "Managing Technology: The Way to Win." These are headlines from a sample of technological articles featured recently in the business press. The message of the headlines is clear: technology is a potent force in modern business, a force which demands the attention of all with responsibility for corporate vitality and success.

This media hype about technology may, however, engender ambivalent feelings on many boards. On the one hand, the sense of threat and opportunity argues for a strong hand in technology decisions. On the other hand, the arcane language of science and technology and the image of the obscure genius suggest that the world of modern science and technology is reserved for specialists and is unavailable to the board.

Dr. Francis W. Wolek began his career as a geologist at Sinclair Research Laboratories. He was Deputy Assistant Secretary for Productivity, Technology, and Innovation at the U.S. Department of Commerce from 1977-1981. He is now Director of Research for the College of Commerce and Finance at Villanova University.

Directors & Boards, Volume 9(No. 4), 1985.

I intend to show that the board is uniquely situated to influence the most critical, technical issues facing the corporation. As a generalist who has dealt with policy issues cutting across diverse areas of science and technology, I have been forced to think generically about technology and its relationship with corporate strategy. The history of innovation has proven to be a useful lode of strategic thinking about technology.

Breaking Through

Popular thinking about technology focuses attention on breakthroughs which obsolete products and undercut markets. Big Decisions (should management get approval for those massive investments of financial and human resources?) and Big Worries (are the media correct in predicting the demise of your industry via invasion of a new technology?) abound. You're damned if you go ahead and end up with another loser like the autogyro; you're damned if you don't and miss out on a winner like the computer.

At first glance, the prospect for coping seems bleak: How can the board predict discontinuities in technology if the firm's own R&D staff has not; how can the board monitor the complex and secretive world of international technology; how can the board winnow the few, sound ideas from the many crazy ones. These and similar questions suggest that it might be best to simply accept vulnerability and make brainpower available for a rapid response to others' breakthroughs.

The history of technological innovation argues otherwise. Not only can the board play a critical role in understanding breakthroughs, but the knowledge gained provides needed insight for strategic evaluation of the company's R&D portfolio and management team. The story of the DC-3 is an illustrative example. [See sidebar.]

A friend recently related a "sad lesson" about scientists and technologists on the board. He had convinced his fellow board members to elect an internationally prominent scientist, only to find that the person acted as a businessman and eluded involvement on scientific questions. The DC-3 development shows us that the scientist was not being contrary, but smart! Understanding of the commercial context dominates understanding of the technological.

Understanding the generic characteristics of technology allows the board to think strategically about

technology. So armed, the issues are not what is the best way to design a propeller, or what is the solution to that annoying vibration problem, or what is the most useful theory of streamlining. These are issues for technologists and their managers. The issues on which the board must demand clear explanation center on the strength of the commercial context which determines success. Specifically:

- ☐ What is the direction of the converging *business* forces (market needs, supplier capabilities, public policies) and are they strong enough to create a new commercial context.
- ☐ In reference to this context, what are the *interdependencies* which determine the commercial and technological capability for a competitive performance?
- ☐ In reference to these interdependencies, what is the *competitive position* of the firm in existing talent, experience, and market position.

Technological overshooting

The firm may sidestep this need for business judgment and give its best scientists and engineers the freedom to choose. However, then it runs the danger of the technological overshooting which bankrupted Rolls Royce on the RB 211 jet engine. Sidestepping is also possible by sticking with safe technologies until the business context is clear. But then the firm runs the danger of undershooting commercial opportunities as did Boeing, which built on improved, military planes (the 247 was an outgrowth of the B9 bomber) when it had all the talent and knowledge Douglas used on the DC-3. The breadth and experience of the board place it in a unique position to provide an alternative: the vision and judgment needed for an ambitious and realistic objective.

Before going off the deep end on the wonders of technology, we must rein in tightly and remember why the

Power of Convergences: The Development of the DC-3

To most people, a breakthrough appears to be an inspiration of genius. At a point in time, a brilliant person shouted "Eureka!" and the new idea was born. The development of the DC-3, the innovation which initiated American preeminence in air transport demonstrates a different phenomenon — *convergence* of existing thinking to a new system.

The designers of the DC-3 integrated several existing technologies — variable-pitch propellers; movable flaps; edge-mounted radial engines; and air-body streamlining. Each of these converging ideas had been under development for 10 or more years and each had been incorporated in a commercial airplane (e.g., the Lockeed Orion, Boeing 247, Northrup Gamma, etc.). Each idea had improved the performance of airplanes. However, each had also disappointed designers by failing to yield the superior performance hoped for and necessary for commercial success.

Undaunted, each design team had continued working to perfect favored technologies, and the resulting sequence of improved models presented visible lines of development from which all could learn. Companies competing in the air-transport market were not only marketing improved models, they were also diffusing knowledge about aeronautical technology.

A key to understanding this successful convergence of technologies is that it was a change in the *structure* of air-transport technology. The DC-3 was neither a simple combination of four lines of development, nor did any particular feature determine its performance. The essential element was design as an integrated system: the design of each element was tied to the design of others. The DC-3 was more than creative emulation; it was an integration which required much in talent, experimentation, and practical knowledge of air transport.

The argument that breakthroughs are understandable may be interesting, but it does not deliver on the promise that the board is uniquely situated on technology strategy. The commercial interplay which paralleled the DC-3's technological development adds the necessary depth by showing that the DC-3 also emerged from a parallel convergence in *market* forces.

As interest in air transport grew, there was greater interest in larger loads, faster travel, and more economical operation. Greater interest also meant a need for airfields at secondary cities with shorter runways. Such were the converging market needs, and a reexamination of the technological convergences shows an interesting pattern: the converging technical ideas also, and not accidentally, satisfied such market forces (engines/payload, streamlining/economy, flaps and propellers/short runways).

The underlying message of the DC-3's development is this: Specialists in propellers or hydraulics were needed to design the next device, but experienced industrialists were needed to understand business trends and risk major resources invested in a new technology, a new form of technical partnership (with American Airlines), and new markets. The engineer can design the device, but the board is uniquely situated to appreciate the venture as a business and to assume the necessary risk.

experience, breadth, and judgment of the board are crucial. Our understanding of technological convergence does not dictate our business judgment. It is the other way around! The critical questions center on the commercial convergences which would create a business opportunity, and the convergences in a particular industry which could create new forms of partnership of complementary interests and capabilities. For these forces to be understood, the board and the firm require both knowledge gained in direct contact with other firms and experience gained from exploratory ventures. Until these steps have yielded a specific group of consumers or customers which can be targeted with a specific business capability, technological progress will remain laboratory novelty rather than competitive exigency.

Following Up

Creative breakthroughs which make and break businesses are the stuff of headlines. However, the investments a firm makes or fails to make in automated production can also determine success and survival. Process investments involve such large commitments of funds, professional effort, and time that they have had substantial impact — both in bankruptcies from overinvesting and big gains from determined adaptation to new demands.

The argument behind investments in production technology is typically that of productivity improvement. Most managers have faith that robots, computers, and semiconductor instruments will do it better, faster, and more smoothly. In all too many cases, however, the dreams of technological wonders go waning while the demands of creditors become pressing.

The work of economists of industrial processes provides evidence that the popular faith in productivity gains is a dangerous simplification. Specifically, they have found that new process technology generally does *not* yield productivity gains which provide an economic return greater than the cost of capital. In other words, companies which justify their slowness on grounds of inadequate return are right — as long as they stick with productivity as the sole source of return.

This analysis of process productivity is counterintuitive and disturbing. If you can't believe in productivity, what can you believe in? The history of process technology in the steel industry teaches some important lessons. Technologies such as the basic oxygen furnace, continuous casting, and the modern blast furnace continue to be highly regarded, despite the fact that their return from cost savings has not kept pace with the cost of capital (e.g., only 5–9 percent for continuous casting). Why the faith? The technologies have had a multitude of things going for them, both predictable and not, and most have not been evident until they were deployed in commercial use.

A simplistic response would be that companies should always invest in technology, because somehow, someplace, someone will find a payoff. If this were true then several steel companies would be heroes and not bankrupt. Instead, the task is much more demanding of commitment and hard work. Technologies such as continuous casting have not really been profitable, just essential for survival.

Adaptable technologies

Modern steel technologies have allowed companies to adapt to a different competitive environment than existed when the investments were made. The adaptation has come at a high cost and required many years. Product lines were changed, new material balances used, supporting technologies tied in, people reorganized, and management adapated to new needs and skills. The key to the technologies themselves was they, unlike predecessors such as the open hearth, were *adaptable*.

Applying these lessons of history to the concerns of the board requires additional insight; specifically, answers to such questions as:

☐ Some technologies have more synergistic payoff than others. How do you know the difference?

Worry About Complacency

An important time for the board to pressure management occurs when new competitors develop a potentially critical and competitive technology.

At such times, the board may have to deal with a complacent management which argues that the competitor is more a joke than an alternative. Arguments will be made that the firm's technology was never improving more rapidly — gas lights were undergoing their most rapid improvements when the electric bulb was introduced — and that the new technology doesn't really work (ball-point pens kept skipping and leaking).

The board must not be put off by such arguments, which typically apply to innovations before learning from use improves them into unbeatable replacements.

As to who is crazy enough to give a crude technology its birth, the usual answer is operatives in small market niches (diesel locomotives were first used in switchyards where fire and steam created hazards). Guglielmo Marconi benefited from another common pattern: accidental discovery of a market niche. He had dreams of a monopoly over a new system for international news broadcasts. Instead, his radio earned respectability, capital, and experience meeting new regulations for ship-to-shore communications — an unforseen, legislative response to spectacular sinkings as the *Titanic*.

☐ How can you tell if the plan for a technology's adoption is both consistent with the market and financial position of the company and includes the time needed for absorption of synergistic benefits?

☐ How can you be sure that the organization will persevere and learn how to integrate a new technology?

The board member's ability to differentiate technologies with synergistic potential depends on experience with the system of procedure, material flow, and driving requirements which structure the firm's operations. Such experience is essential to understand where the three hallmarks of critical technologies apply: adaptability to future change; simplification of the system; and/or significant impact on people.

Competing designs

A characteristic of critical product or process technologies is that they involve such large commitments (designing all the system interfaces, readjustment as application divulges more ramifications, managing an interdisciplinary team with different languages,' etc.) that the firm must often choose one of several, competing designs. Such critical choices have determined the success of nations as well as companies. For example, in the field of atomic power, the United States chose pressurized-water technology and won the early race to commercial markets while the British chose the technologically more sophisticated high-temperature gas reactor.

One difference between companies which reap profit from technology and those which reap sterile knowledge is that profits flow from *managed learning*. The most important knowledge gained on critical technologies will not be from the lab, but from the shared experience of process engineering, sales, materials management, and line supervision working together from initial analysis to fully integrated operation. That is, profitable experience centers on the "*know-how*" of technology — how to keep it in reliable operation, how to adapt it to other technologies, how to create a new product line integrating the new capabilities with market opportunities, how to build a team of people committed to the technology.

Reason for failure

Firms which fail, despite investments in perfectly marvelous technology, are those which focus on productivity gain, believe that machine installation is machine utilization, and rely solely on engineers for implementation. Those steel companies which delayed adoption of critical technologies typically believed their world-class engineers guaranteed a competitive ability to respond quickly once the technology was proven by others. Such abdication of management in favor of engineering overestimates the importance of abstract principle and deprives the engineers of the critical support they need.

Change in people's self-perceptions, product lines, and operating practices do not follow the visionary pace of dreamers, journalists, and missionaries. Instead, the history of technology teaches that change is so long and meandering that it is helpful to think of it occurring in stages.

The board's fiduciary responsibilities for the financial and human resources of the firm place it in a unique position to critically review plans for the deployment of process technologies. In confronting the contest of such reviews, the board should find the firm emulating the practice of "roll outs" used in marketing new products. That is, a phased deployment, involving:

☐ First, a test on existing tasks to learn the technology's operating characteristics (test marketing to learn consumer requirements).

The Need for Champions

Full commitment and active involvement by top management are necessary for the success of critical technologies. This is one of the primary lessons of the history of computer technology.

Only a mother can love an ugly baby, and the computer, like many critical technologies, was ugly in infancy. It took fortitude — and government contracts — to persevere when the general view was that there was no demand, no dominant design, and substantial risk of loss.

Top-level champions like Thomas Watson were needed to commit the funds (many companies starved their early efforts), absorb huge losses on experience-building contracts (the "Stretch" computer cost over 10 times its contracted price to the Atomic Energy Commission), build quality peripherals (many contracted these out), approve risky marketing plans (some would not accept the risk of leasing to customers), avoid destructive disputes between technologists (the choice of transitors vs magnetic amplifiers was a critical choice which had warring advocates), and be dedicated to consistent improvement over time (several companies tried to market obsolete technologies).

The board should not play "bet your company" and approve a dream technology unless someone who has already arrived is willing to play "bet your career." The personal commitment of champions with top responsibility is essential to command the respect of financial sources, be able to objectively choose between technologies advocated by people competing for the top, implement marketing and organizational plans that make the technology effective, and persevere through unexpected adversity.

[ ] Second, commercial use in a market niche to understand integration needs (first market entry to learn how the product relates to distribution and competition).

[ ] Third, focused use of the technology on a product group to translate lessons into a working organization (regional focus to build a marketing system).

[ ] And fourth, adaptation for use across product areas (national marketing of a product line).

"Use it or lose it" is the password on critical technologies. If deployment does not occur with the active guidance of top management, the firm will lose its competitive position regardless of the sophistication of its technologists. Using technology in practice is a process of:

— top-down highlighting of potentially critical technologies;

— phased deployment in operations;

— managed learning of benefits;

— bottom-up communication of refinements, interdependencies, and resource needs; and

— top-management structuring of the organization, time table, and directions for change.

Maintaining the Lead

The history of innovation also imparts lessons on the normally long periods of steady improvement in an existing technology. For example, the full impact of a critical technology takes many years and involves many steps of modification and refinement to fit many changes in the market. Thus, it should be no surprise that most of corporate R&D is a process of *incremental* improvement based on actual experience. Incrementalism — e.g., accumulations of 10-percent improvements in cost, adaptations of design to more varied conditions, resolution of problems as operations are scaled-up in volume, etc. — is the life blood of corporate R&D.

We also know that breakthroughs result from accumulations of converging developments which originate in many different organizations. Thus, it should be no surprise that much of R&D is a process of "building windows on the world" — developing the reputation and talent to have access to progress at other organizations.

Finally, given the importance of building an expert team to assure managed learning, it should be no surprise that most organizations become committed to their own specialists and their own pattern of progress. The functional narrowing of perspective (denounced as the NIH or "Not Invented Here" syndrome) sometimes has the disfunctional consequence of rejecting ideas originating elsewhere. Indeed, entrepreneurs who had to fight unreasonable resistance to establish their technology have turned out to be some of the most narrow-minded opponents of the next wave of technology: Western Union resisted the telephone, AT&T resisted radio, Marconi Radio resisted radio communication of voices, and RCA resisted FM. (However, the resistance of RCA to FM, and computers, also was partly brought about by the magnitude of their commitment to television.)

Big bucks, snails pace

The technology expert generally reigns supreme during the normal pattern of incremental progress in

Risk and the 'Rule of Sevens'

An undeniable board function is validating the resource commitments required for success. Economists who have studied R&D have found an exponential increase in resource needs which may be simplified with a "Rule of Sevens": If an incremental technology, to be sold through existing channels, costs $1 million for R&D (i.e., to a set of specifications), it will cost $7 million for design (i.e., completion of an operating prototype), and $7 million more ($15 million in total) to produce the first commercial unit (i.e., technology refinement, plant tooling, documentation, promotion planning, training, etc.).

Furthermore, these estimates do not recognize the working-capital requirements of market expansion — e.g., special promotions, training the service organization, stocking the pipeline, production scale-up costs, etc. — which precede significant profits.

Studies of the lead time in innovation are also enlightening. If the time to complete the research was one year, the time to the first unit will be three years, and significant profits will not start to flow for another two years (i.e., a total of five years). Furthermore, any good business leader has learned the hard way that it is foolhardy to believe it will never rain on your parade.

Risk is one of the fundamental characteristics of innovation. It seems helpful to factor this overall risk into the risks of: technological success (i.e., the thing will work); commercialization (i.e., management believes it continues to make competitive sense and authorizes deployment); and commercial success (i.e., the customers like it and use it). On average, the probabilities of an incremental advance successfully completing each stage are: .6, .6, .7, respectively, with an overall result that only one in four projects is successful ($.6 \times .6 \times .7$).

These data are sobering indeed, but even more so when we realize that the definition of success was only that the project will get the firm back to where it started (i.e., it returns its cost at a rate equal to the cost of capital).

technology. Insofar as changes are incremental and the firm has built a tight organization of mutually dedicated experts, this situation may seem to provide valid relief for the board. Don't fix what isn't broken and don't tamper with success.

However, it is not uncommon that executives and/or technologists become impatient with the pace and direction of progress. What may then emerge is a Big Project — the "exciting, new direction that will shake the industry." Now the board is heavily involved and must not be lulled by smooth progress in the past.

Not radical enough?

To be sure, questions about convergences, critical linkages, life-cycle planning, etc., are important. But what if management's answer is that the change is big, but not radical enough to obsolete the existing structure.

Be very, very skeptical! Management can easily underestimate the synergistic effects of change and overestimate existing talents to process it. If it is big enough to shake the industry, it is critical enough to require phased deployment, planning, and market convergence.

Technological innovation is risky, expensive, and long. Innovation has made and broken many firms. The resources required are more substantial than many realize. Technology has great potential, but only the foolhardy ignore reality. Since foolhardy organizations may not survive, there have to be ways of adapting to these realities. One such adaptation has already been noted — R&D becomes an organized process of incremental advance, so that its lessons are cumulative and even failures yield useful knowledge.

One problem with incremental R&D is that people who share a common commitment can become provincial in their thinking. It is nice to have an R&D lab which believes it has no peer, but this is also a clue that the company may have become muscle-bound.

Beware and never accept the claim "We're the best in the business and have nothing to learn from others." The world of international science and technology is entirely too rich and complex to ever make such a statement valid. The technology of unit-body construction crossed and re-crossed the Atlantic many times — Vauxhall used it in 1903, Renault, Fiat, and Peugeot provided a model for U.S. engineers, and Ford and Budd provided designs and tooling for Volkswagen. So too are suppliers an important source of technologies — disk brakes, solid-state alternators, paint and lacquers, etc. — which require continual redesign of process and product features.

An irreplaceable role for R&D is to integrate the company with the network of experts whose interactions are determining the rate and direction of innovation. Work at the cutting edge of progress takes place in interpersonal interactions between reputable people and is only shared with those who can give information as well as receive it and who have the hands-on experience needed to ask intelligent questions and understand expert replies. In short, the firm needs top scientists and engineers and needs them to be in touch with other leaders throughout the world.

Making Profits

The development and early commercialization of a major technology will undoubtedly be a trying, unpredictable, and expensive process of learning which will thoroughly test a board's perseverance. Certainly when these trials have been passed, and wisely marshalled resources have produced a brilliant technology, the board may sit back and watch the profits roll. Sorry to say, such thinking implicitly assumes that scientific and technological issues determine the success of innovations. The posterior trials of technological development turn out to be as equally demanding as the prior.

The history of technology is replete with tragic cases of brilliant people who persevered through adversity to produce terrific technologies on which others made millions. In most cases, failure followed from errors in business judgment due to overestimating the commercial value of brilliance, underestimating the competition for profits, and greed.

The case of a bankrupt company featured on Public Broadcasting's "Enterprise" series highlights the importance of business judgment in selecting the correct home for a technology. The company had pioneered an innovative computer terminal in

Director's Duty: Stamp Out Greed

Brilliant technologists may be covetous people who do not want to share profits, equity, and managerial control. If you are on a board that must deal with this attitude, your responsibilities to bring about change are great, for the history of innovation suggests it could turn out to be a spiteful and self-destructive failing.

For example, Eli Whitney is widely regarded to be one of the more brilliant luminaries in American technology. However, instead of earning millions from the cotton gin, it put him in the poor house. When his invention won spectacular acclaim, he rejected many proposals to license the technology to others and insisted on personal control of the technology and its markets. Unmet demand, because Whitney couldn't grow fast enough, is a powerful vacuum; and Whitney found that others modified his designs to build their own gins. He wrote blistering letters and fought back in court, but only the lawyers won. He went broke.

the days when office automation was in its infancy and found a niche that no one had predicted. Sales soared, officers seemed to become millionaires, and visions of a future IBM clouded the horizon. Sure of their technological brilliance, management turned down repeated offers of acquisition. They felt they had the brains to make their own home base and were not going to sell their future short.

The story is an oft-told tale of people who overestimate their smarts and underestimate the resource requirements of a successful business. The story ended in bankruptcy after a few bright years of valiant efforts to meet the competition and to fund rapidly expanding markets.

Existing cash cow

What many forget about phenomenal successes like IBM, Texas Instruments, and Xerox is that companies need considerable resources to build an organization and competitive strength. In each of those cases, the company had an existing cash cow to provide a stable platform of capital generation and a service organization.

Maybe the worse thing that can happen to a technology-based company is to have its products succeed brilliantly and its markets develop rapidly. Such results attract predators and generate punishing requirements in management and capital.

The adaptive response of a free market to the realities of success has been an evolving system of relationships between big and small companies. One element is the buyout — now being experienced by the small companies that absorbed the high risk of innovation in robotics. They proved that a market exists and started building know-how in special niches such as automated painting. Now that the start-ups are facing the rigors of big-time competition and the resource requirements of national markets, they are being acquired by the GMs, GEs, and Westinghouses.

Invent it, sell it

This story, repeated in many fields, yields one entrepreneur's motto: "Invent it, grow it, and sell it!" Since the rewards to entrepreneurs in such buyouts are substantial, this system has been an engine of technological leadership. The system works. The board and top management's responsibility, then, is that of timing.

Competition is the fundamental force in a free-market system, because free competitors will try anything legal to do each other in and become a hero by appropriating profits. Unfortunately for technologists, their background — often in the academic world where the originator of ideas is the hero — and their own fascination with gadgets can lead to underestimation of the prowess of businesses hunting profits.

The history of competitively successful innovations repeatedly demonstrates that ideas are easily discov-

ered ("reverse engineering"), patents can be designed around and fought in court, and technological superiority can be neutralized with business savvy (marketing, service, control of distribution, etc.). In short, the rules of the game when the board considers the firm's competitive position are:

☐ Neither trust the cloak of secrecy, nor let people photograph your technology.

☐ Be prepared with the funds and allies for a patent battle.

☐ Never allow management to underestimate the competition.

The Pros and Cons of Union Members on Boards
Leading experts offer some advanced thinking on the issue.

Lucrative offers

The fact is that companies do pay handsomely for patent rights and do reward successful entrepreneurs with lucrative buyout offers. The buyouts are especially handsome when the entrepreneur has the time and skill to build an organization with competitive know-how. However, it is always best to assume such payments will not be greater than the costs of getting around a proprietary position. In short, unless a firm has the millions for a long market and legal battle, it shouldn't be greedy.

Technological innovation is a team effort from start to finish. Scientists and engineers who are not tied into the network of leaders in their field are sure to miss the boat. Entrepreneurs who fail to build know-how through working with users and suppliers will end up dead in the water. Boards who understand that technological success is a team effort are prepared to share handsomely.

Leading the Way

I have been very privileged in my life to travel widely among the centers of technological progress in America. The sophisticated use of man's knowledge I have witnessed, the ingenuity in adapting it to new needs, and the genius in building the resources of people and capital into competent competitors have been awesome. The ideas, the sacrifices, and the repeated attempts to solve problems with the raw tools of intelligence and back-breaking effort just don't stop.

America is blessed with the people, riches, and social system to be the engine of progress for all mankind. The rest of the world knows that, gains excitement from us, and refuses to let us shirk our responsibilities. We have no choice as a nation; our own dreams and those of the world will not let us off the hook of discovery, adaptation, and growth.

You as a corporate director also have no choice. You cannot stop society from molding the corporation into an effective force for its aspirations. The social pressures, raids from all quarters, and internal demands of people are no passing fad. We haven't seen anything yet, and our ability to innovate will be as much a cause as a source of relief.

Just as you cannot stop the dreams and progress of society, you cannot stop the progress of technology and the ingenuity from which it springs. You may personally stop and get off, but the competition and opportunity which are at the heart of our system will replace you with others who will welcome the challenge.

Sense of opportunity

My intention has been to inspire the confidence and pride that are needed to use your unique position to serve. As a group, corporate directors have the richness of experience and breadth which is essential to understanding the convergences, nature of building know-how, and importance of world-wide learning. As senior officers, you have the sense of wonder and opportunity and the balanced understanding of business needs to inspire professionals. You have the freedom from operating responsibilities to listen and make the critical decisions which transcend organizational boundaries. You have the ability to understand technology and to place it in a positive context of shared progress. And, in a land where ownership is truly in the people, you speak for all as industry's stockholders.

A board of directors has a unique and special contribution to technological progress. What we need from you is the vision, energy, and the courage to make it. ■

DISCUSSION

Mr. WALGREN. Thank you, Dr. Wolek.

Are you concerned about the trend the first witness mentioned to restrict the transfer of information among certain Government-funded research programs if we are to have this kind of openness that you are emphasizing in an interactive sense? Some of the limitations on publishing that we have seen from the Defense Department would be inconsistent with that, wouldn't they?

Dr. WOLEK. Absolutely. But I am less concerned about the limitations on the publishing. I have no problem with asking authors to send in a paper and check it over and look for things in it that might be detrimental to national security.

The whole philosophy, though, behind that move is what bothers me, because how can you control what the people say in their interactions at conferences, during their visits to other facilities, during the visits that they get from other facilities? It is impossible to control that type of thing, and that is where you get real transfer of know-how, the understanding of the type of thing that never appears in the papers.

The only way that you can stop the transfer of know-how is to stop the interaction. What I am saying is, as soon as you stop the interaction, you stop the effectiveness of the applied scientific work in the mission agencies.

Mr. WALGREN. I see. Let me ask the gentleman to my right and left if they would like to raise any subjects. If not, we should close at this time.

OK, on behalf of the task force, let me express my appreciation of your being available for this work and these discussions. We certainly appreciate your contribution to it.

Dr. WOLEK. Thank you, Mr. Chairman.

Mr. WALGREN. Thank you. Our hearing will be adjourned.

[Whereupon, at 12:18 p.m., the task force recessed, to reconvene on Wednesday, October 30, 1985, at 8:30 a.m.]

APPENDIX 1

TESTIMONY OF JOSEPH M. PETTIT, OCTOBER 27, 1985,
HOUSE COMMITTEE ON SCIENCE AND TECHNOLOGY

(IN LIEU OF SCHEDULED APPEARANCE, OCTOBER 24, 1985)

By way of introduction, I am Joseph M. Pettit of Atlanta, Georgia. I have been president of the Georgia Institute of Technology since 1972. Prior to that I was on the faculty of Stanford University from 1947-1972 , serving as dean of the School of Engineering from 1958 to 1972.

I am one of the eight original presidents on the DOD/University Forum. I was a member of the National Science Board during 1977-1982. I am a member of the National Academy of Engineering, and chairman of its Education Advisory Board.

The interest of your current hearings extends over a wide range of matters involving the research roles of the mission agencies. I was asked to comment in particular on some aspects which have been under consideration by the DOD/University Forum. Even these constitute a wide range, and I believe my contribution to the hearings might be most useful if I concentrated on one issue alone.

I should like to comment on the appropriateness of DOD, as a mission agency, in supporting basic research in the universities. A question which is sometimes raised is, might it not be better for such research to be supported only by a specifically designed agency, such as the current National Science Foundation, or perhaps a wholly new department? My answer is no: I support the current arrangement instead. Let us encourage the mission agencies, including DOD, to carry a solid responsibility in helping to support basic research in the universities.

Historically, prior to World War II, the military agencies which now comprise the Department of Defense, did their research largely through their own laboratories, and most it was applied, or mission-oriented. Little attention was paid to building up our knowledge base, upon which future defense systems would depend. Little use was made a national resource well suited to extending our knowledge base in science and technology, namely the professors, researchers and students in the universities. During WWII this pool of talent was mobilized in several wartime projects and laboratories - to great effectiveness. But after the war these persons returned to the university world - which has its own unique environment. Universities are institutions of higher learning, where fine minds come together to learn and teach, and especially to extend the frontiers of knowledge in the various disciplines. Indeed the universities are the strongholds of the disciplines, in which are built the foundations upon which interdisciplinary work in applied research and development can best be done, including of course that which will later be

carried out in the mission oriented work of the various Federal agencies.

This national resource in the universities was, at the end of WWII, newly appreciated by many, and articulated by Vannevar Bush and others. A new agency was proposed for engaging this resource, and in 1950 there was finally established the National Science Foundation. But in the interim after 1945, the defense agencies stepped into the vacuum, led by the Office of Naval Research. They extended the previous horizons of the defense establishment as to the range of research which should be supported. They established new contracting mechanisms well suited to working with universities, as opposed to their usual dealing with defense suppliers of goods and non-research services. Speaking personally, I had a very satisfactory experience with one of Stanford's first ONR contracts, commencing in 1947 and extending for eleven years.

As the other agencies, Army, etc. joined the ranks of research supporters, there developed a cadre of technical contract officers, dedicated to support of basic research, though always with knowledge of the applied needs of their agency. Rapport with those of us in the university developed well, and much was accomplished. Finally, when NSF was established in 1950, its officers merely joined the already existing group of informed contracting officers.

I refer to these officers as a "group," because they did not work in isolation from each other. We had annual meetings on the campus, to bring them up to date on research results of the past months, and our suggestions for continued work. One or another of them would usually pick up on the worthy suggestions, perhaps one of them who saw particular relevance to the development work in his agency, but sometimes merely the one who happened to have the budget money at the time. But on one or more occasions some one of the contracting officers seemed to possess a certain unique vision or intuition that caused him to pick up support of an idea that later proved to have wide value, far beyond the needs of his own agency.

The point to this narrative is that wisdom as to which of the infinite number of possible avenues of basic research might be promising for support is widely distributed among many individuals and agencies. The nation and the universities themselves are well served by having a diversity of sources of support.

A final point on the diversity of wisdom. Some of this wisdom resides in the universities themselves, of course, and if we could have a little "venture capital" to pursue some potentially valuable new initiatives, the whole enterprise would be well served. Thus I would urge that we be allowed the equivalent of the Independent Research & Development (IR&D) expenses permitted

to industrial contractors. At Georgia Tech, a few percent of our approximately $90 million of sponsored R&D would facilitate the exploration of some new ideas that might later become significant contracts themselves.

Another point of view on basic research derives from a now well established consensus that a small fraction of corporate or federal expenditure should be an investment in the future, through research and development. This philosophy could well be a part of the thought and responsibility of each Federal agency, including especially the mission-oriented ones like DOD.

Finally, the financial resources to do this must be maintained at adequate levels. We have been much concerned with this in the DOD/University Forum. In DOD budget parlance, it is the 6.1 and 6.2 monies that are the most significant for university research. The total amount has not been great, and it declined seriously during the 1970s. This past year, through the "University Research Initiative," some of this loss was restored. This must be continued. Basic research money is always in jeopardy because of competition with expensive projects with immediate urgency. Somehow it seems easier to postpone the future. But the future cannot be postponed nor predicted.

The continued support of members of this House Committee on Science and Technology will be much appreciated.

R&D LABORATORIES' ENVIRONMENTAL CONTEXTS: ARE THE GOVERNMENT LAB-INDUSTRIAL LAB STEREOTYPES STILL VALID?[1]

> The government research organization is not troubled by the types of pressures that afflict the industrial or university research laboratories. The government laboratory is not concerned with either seeking to contribute to corporate profits or contributing to fundamental knowledge in a highly competitive publication race. [Marcson, 1972: 175]

Introduction

Stereotypes are an often useful shorthand. In the making of science policy, as in much of human endeavor, stereotypes can facilitate communication and decision-making by reducing the need for elaborate description and qualification. Consider for example the "basic-applied research" stereotype. It is not a precise term yet there is enough commonly held meaning in the distinction to warrant its use not only in casual discourse but in public policy as well.

Our study examines another stereotype, one almost as venerable as the basic-applied convention. The concern here is with the stereotypes pertaining to the environmental setting of R&D labs, particularly assumptions about differences between government and private labs. The stereotypes associated with the government-private lab distinction are based on concepts somewhat less murky than basic-applied research.[2] It is possible to identify some R&D laboratories which nearly everyone would view as government labs and others which nearly everyone would view as private. But of course, the clarity of concepts and the validity of stereotypes bear little relation. Even if one perceives that one lab is clearly a government lab and another is clearly private, one is not required to assume that the former is not market-driven and the latter is immune to political control.

One might well ask why the government-private laboratory stereotype, a comfortable and apparently useful simplification, should be subject to scrutiny. Our answer is two-fold. In the first place, there have been widespread societal changes in organization forms and environments (Aldrich, 1979; McKelvey, 1981; Pfeffer and Salancik, 1978) and it is unlikely that R&D laboratories have been unaffected by these broader trends shaping the structure of organizations. The emergence of new forms of organization has been widely documented (Sayles and Chandler, 1971; Chandler, 1962; Evan, 1966; Walsh, 1978) and, more specifically, the blurring of traditional government-private organization forms has received much attention (Bozeman, 1984; Fottler, 1981; Allison, 1983; Rainey, Backoff and Levine, 1976; Muslof and Seidman, 1980). R&D laboratories have not been immune to the process of organizational change as illustrated by the proliferation of cooperative and interorganizational research operations that have recently developed (Nelkin, 1972; Farris, 1978; Rothwell and Zegveld, 1982; Bozeman and Link, 1983; Reppy, 1977; Toren, 1978; Mowrey and Rosenberg, 1982). But the validity of government-private lab stereotypes is not an issue of concern only to students of organization change. Public policies are made on the basis of assumptions about the distinctive competencies, liabilities, and performance of labs in various institutional settings and environments. If these policy relevant assumptions are based on worn, threadbare stereotypes it is worth knowing.

Our examination of the environmental context of R&D labs is presented in two sections. In the first section, 250 R&D laboratories are classified first according to "ownership" (i.e. the conventional

public-private distinction) and then according to the "publicness" of organization environments (defined in terms of governmental influence resulting from government funding) and "R&D product category" (defined in terms of the market-orientation of the R&D output). This taxonomic effort concludes with the presentation of a conceptual framework applicable to R&D laboratories regardless of ownership type. In the second section, 32 detailed case studies are examined and classified in terms of the conceptual framework developed in the first section. From this analysis, a number of hypotheses and preliminary conclusions are generated about the effects of environmental context on R&D laboratory behavior. The paper concludes with a brief elaboration of the significance of the findings for R&D policy.

The Changing Environmental Context of R&D Laboratories

Students of R&D management have, by and large, been more attentive to the structure and design of the lab than to its environmental context. Studies examining such issues as communication (Allen, 1970, 1977; Moser, 1983; Stahl, 1975; Stephenson, 1971), coordination (Evan, 1966; Stahl, 1978; Marquis and Straight, 1966), and productivity (Irvine and Martin, 1980, 1983, 1983a; Andrews, 1979; Argyris, 1968; Stahl, 1977; Box and Cotgrove, 1968) have focused on the behaviors within individual labs and given scant attention to interorganizational relations or other such environmental interactions. The effects of environmental context on R&D labs have not often been examined and typically, assumptions about environmental influences on behavior are based on conventional wisdom and are not the target of systematic inquiry.

Simon Marcson (1960, 1966, 1966a, 1968, 1970, 1972) is one of the few scholars who have considered the impact of environmental context on R&D labs and much of his work is supportive of traditional stereotypes. In a 1972 study, Marcson identifies four basic environmental settings for organizations engaged in research: industrial, governmental, university, and non-profit. Each of these contexts is based on the formal legal status ("ownership") of the labs. Marcson argues that ownership of the R&D lab is the most critical variable in predicting organization behavior.

Marcson's treatment of the ownership variable is based on traditional assumptions about differences between public and private organizations. If a laboratory is owned by an industrial concern it is assumed that it will behave according to the standard rules of the firm in the market. If a laboratory is owned by a government agency, it is assumed that theories about bureaucracy, political decision-making and other political economy related theories prevail. The use of an ownership-based taxonomy for reclassifying R&D laboratories is pervasive in the literature (Pelz and Andrews, 1966; Fusfeld and Langlois, 1982; and Bigoness and Perrcault, 1981). Even the few comparative studies of R&D laboratory performance focus largely on differences based on public-private sector ownership (Stephenson, et al., 1971; Evan, 1966; Marcson, 1972; Loveless, 1985).

Ownership and Environmental Context

We assume, with Marcson (1972), that the environmental setting of an R&D laboratory is a vital determinant of its behavior. But the traditional ownership distinction, based as it is on formal legal status of

the organization, is an incomplete and in some ways misleading indicator of environmental context. Particularly inappropriate is a strict dichotomy between government and private labs. Ownership type does not inalterably determine R&D type and product, management structure, or effectiveness and efficiency. Certainly there is likely to be similarity among, say, government-owned labs, but there is also much diversity and, more to the point, certain government labs are more similar to privately-owned labs than to other government labs.

The recent history of R&D labs in the United States illustrates that ownership is often a poor guide to behavior. Consider the fact that since 1940 several completely new forms of R&D organizations have evolved. It is now not uncommon to find on a university campus an industrially funded proprietary research center, a joint industry/ government funded generic research center, or a government owned university operated research center. Similarly, in the 'private sector,' high levels of government support and control of the conduct of research in industrially owned R&D laboratories has become commonplace. As a result of these changes, it should not be surprising that it is becoming increasingly difficult for both scholars and policymakers to grasp the complexity of the R&D laboratory network. Furthermore, it can be expected that with the passage of such legislation as the Bayh-Dole Act (PL 96-517) and the Stevenson-Wydler Act (PL 96-480) that R&D laboratories will continue to change from the stereotype of being either a government lab or an industrial lab. As a result of both of these Acts, many 'government labs' are not only very much in the business of technology transfer, but are becoming increasingly subject to some of the

57-279 O - 87 - 26

same market viscissitudes as traditional private sector labs (Department of Energy, 1984; Department of Commerce, 1984). Presently, scientists in U.S. national laboratories are able to share in the profits of patents they produce and the pecuniary incentives in public and private labs are becoming more alike (Technology and Information Policy Workshop, 1985). Marcson's (1972, p. 173) observation that research organizations in different environmental settings "develop an atmosphere or climate within which the individual functions" is as true today as ever, but one cannot conclude that ownership type is the central feature dictating atmosphere.

Further complexity is introduced by the emergence of new forms of organization (such as the government sponsored enterprise and the multiple organization enterprise) and the formal partnerships among government, industry and university labs. The government-owned, contractor-operated form has a relatively long history (e.g., Brookhaven National Laboratory, Oak Ridge National Laboratory) and more recent innovations in organization forms (e.g., the Federally Funded Research and Development Center, state government-financed R&D "incubators") have further blurred the sectors and, consequently, rendered the ownership distinction more problematical.

"Publicness" and Environmental Context

The breaking down of sector distinctions does not imply that the "publicness" of an R&D lab is no longer significant; instead it suggests the need for a publicness concept based on something more than ownership. An approach developed by Bozeman (1984) provides one means of moving beyond overly simple ownership-based classification of environmental

context. According to this scheme, both industrial and governmental organizations are assumed to operate on a mix of authority types; publicness is measured in terms of the organizations' proportions of influence by political and economic authority. Thus, one might expect an R&D lab at an an aerospace firm which receives 90% of its R&D revenues from government contracts (and is thereby subject to a variety of government constraints) to behave differently than one with little or no R&D revenues from government contracts. Likewise, a government R&D lab which depends heavily on user charges and other quasi-market funding mechanisms might behave differently from one that receives all its funding from discretionary appropriations processes. Indeed, according to such a conceptualization of publicness it is theoretically possible to view a given industrially owned organization as "more public" than a given government owned organization. It is possible to describe the degree of publicness of any organization, even those of ambiguous formal status.[3]

Classification Scheme for the Environmental Context of R&D Labs

The classification scheme employed here focuses on two variables: publicness and R&D product type. These variables are viewed as a simple proxy for the extent to which the organization is influenced by, respectively, political authority and market authority. A nine cell classification matrix is established which provides for the categorization of R&D laboratories according to the two taxonomic variables of interest.

The Publicness Measure

The term publicness could be used to refer to any of a number of characteristics of an organization. As mentioned, the term public organization is often used to refer to government organizations, it is descriptive of the formal legal status of the organization. In economics, public is used to describe the economic character of goods and services. In political science the term public interest is used as a normative indicator of the organization's role in society. We have chosen a measure of publicness which, of necessity, excludes much of what is denoted by the term. But our purpose is to develop a measure which (1) can be applied to any R&D organization, (2) is not confused with normative assumptions, (3) is easily measured, but, at the same time (4) seems to capture an important property of R&D organizations.

Our simple measure of publicness is the percentage of government financing of the organization's R&D effort. In choosing this measure we are assuming that government financing equates, at least to some extent, with public influence. this assumption is not patent but there is reason to believe that it is a plausible assumption (Pashigian, 1976; Baumol and Oates, 1979) and, moreover, one purpose of this study is to provide an indirect test of the assumption.

Using the percentage of public financing as a measure of publicness enables an interval level of measurement. However, at this state of conceptual development we determined that an ordinal measure might be more appropriate. The following categories are used to develop an ordinal measure of publicness:

-- High Publicness: 76-100% of research funded by government agencies.

-- Moderate Publicness: 26-75% of research funded by government agencies.

-- Low Publicness: 0-25% of research funded by government agencies.

While this simple measure is not an entirely satisfactory indicator of publicness, our limited objective is determining whether it yields a distinction as useful or more useful than the traditional dichotomous ownership (i.e. government-industry) distinction.

The R&D Product Measure

As a proxy for market influence, the physical and intellectual products of the laboratory are measured in terms of their imputed market orientation. An R&D product can be thought of as being aimed at a small user group, as small as a single individual or single firm, or, at the other extreme, it can be aimed at the research/technology development community as a whole. The ordinal separations employed here classify laboratories in terms of the dominant orientation of their product. Does the individual laboratory produce a product which is predominantly for limited consumption or predominantly for general consumption. Market influence is indirectly measured as the extent to which the product (whether knowledge or physical device) is appropriable. The specific categories developed for this measure are as follows:

-- Generic R&D Product: A laboratory environment with little market influence. In this case, the principal output is a

physical or intellectual product having the characteristics of a public good.

-- Balanced R&D Product: A laboratory environment with a balance of market-directed and non-market-directed R&D products. In this environment the output is neither dominantly generic nor proprietary (see below). This type of laboratory is not just mixture (since nearly all laboratories produce at least some mix of generic and proprietary products); the key term is balance.

-- Proprietary R&D Product: A laboratory environment with heavy market influence. In this case, the principal physical or intellectual output is, in an economic sense, a private good or output which is targeted for the exclusionary use by a privileged group, usually the firm.

The Classification Scheme

As illustrated in Table I, the classification scheme results in a nine cell matrix which can be used for determining the distribution of laboratories in each cell type. A name has been designated for the environmental context of organizations within each of the nine cells. In each case, the name is descriptive of the relative influence of publicness and the mix of product types. Thus, the Public Generic cell has the characteristics of the stereotypical government lab, funded almost entirely by government funding and concentrating on R&D products which have the characteristics of a public good. Public Generic laboratories are not invariably owned by the government. Independent Market

Laboratories represent the industrial stereotype, largely independent from public influence and producing R&D products geared to the market.

--TABLE I goes here--

The Organizational Population and Its Characteristics

From the universe of North American R&D labs, our study is concerned with a study population of 829 laboratories which are involved in energy related research.[5] As demonstrated in a previous study by Martin and Irvine (1983), it was decided that a focus on R&D labs working in the same broadly defined field would have some advantages for the study. The fact that the focus is on laboratories with some similar output characteristics is beneficial to a study that is interested in determining the impact of environmental context on laboratory behavior. If our study had focused on a random grouping of R&D labs, it might have proved even more difficult to separate out the effects of publicness and R&D product type from the effects of R&D substantive focus.

Since a major purpose of this study is to contrast our classification scheme with the traditional focus on ownership type, it is important to identify the ownership distribution among the focal R&D laboratories. Table II details the ownership characteristics of the 829 R&D labs engaged in energy R&D. This initial classification exercise indicated that ownership categories required modification from the simple government/private dichotomy common in both research and policy-making. In fact, one of the most compelling arguments for a concept of publicness which expands upon the simple dichotomous view of public (govern-

ment) and private (industrial) organizations is the fact that only 51 percent of the laboratories in the study population could be classified as being either government or industrial. Even limiting this analysis to the traditional ownership distinction simply is not practical in light of the fact that so many labs no longer have the simple organizational roots common before 1940.

--TABLE II goes here--

Design and Implementation of a Descriptive Survey

A brief survey instrument was developed to facilitate the classification of the focal R&D laboratories. The questionnaire was intended to gather information about the environmental context of the individual laboratories as well as information about the organizational structure and resource flows of the laboratories. The instrument was addressed to the laboratory directors. After an initial mailing, a second mailing, and a follow-up telephone call, 250 usable questionnaires were received.

An examination of the distribution of respondents according to ownership characteristics (Table III) indicates that two of the groups, cooperative and mixed, are represented in about the same proportions as in the study population. However, the industrial group is somewhat under-represented and the government group is somewhat over-represented.

--Table III goes here.--

Classification of the Study Population

A key component of this study is provided in Table IV which classifies respondents on the basis of publicness and nature of R&D product, the two taxonomic variables of principal concern. The old stereotype, that government labs produce generic R&D products while industrial labs produce proprietary ones, does not work as well as the "new stereotype." That is -- public labs (defined in terms of government receipts) are more likely to produce generic R&D products and less public laboratories are more likely to produce proprietary products. Clearly, public labs are not always government-owned. The results of the classification indicate that laboratories of each type tend to produce a range of products regardless of ownership.

--Table IV goes here.--

The data reviewed in Table V highlight the problems associated with simple ownership based classification. Considering industrially owned laboratories alone we see that only 63% of these organizations produce an R&D product that is either proprietary or strongly proprietary, in its end use. Stereotypical assumptions regarding industrially owned R&D laboratories would lead many observers to expect that all or most of the R&D products of this type of laboratory would be proprietary by nature. While less dramatic, the research product characteristics of the government owned laboratories also deviate somewhat from stereotypical assumptions. Finally, the classification of 160 labs as being neither govern-

mental nor industrial underscores the limitations of the government lab-industrial lab stereotypes.

--Table V about here--

Analysis of the similarities and differences among laboratories classified in the various environments indicates that the publicness based dimensional classification technique does capture similar organizational forms. Table VI reviews a number of characteristics for each of the cell environments. Analysis of these characteristics indicate that, as one might expect, the research objectives of the various laboratory types move from basic to applied with decreasing levels of publicness and with increasing market influence. This observation holds for all laboratory types, regardless of individual ownership characteristics. Regarding the level of governmental influence on research goals, even among those lab types with a high level of publicness, there is a decline in the level of government influence as market influence increased.

--Table VI about here.

Case Study Evaluation of Selected Laboratories

The classification matrix developed in the previous section separates R&D laboratories according to environmental influences. The results of implementing this taxonomy led us to the preliminary conclusion that variation does occur between the laboratories classified in

each cell. This level of analysis, however, offers little in the way of assessing structural/behavioral organizational differences. In order to identify these differences at the organizational level, it was necessary that several individual organizations of each lab type be studied in greater detail. Only through a close analysis of individuals from each form can it be fully determined how they are different, and just as importantly, what some of these differences tell us about our continued use of the government-industry lab stereotypes.

The Case Study Design

The objective of the field research was the identification of the organizational characteristics for each of the R&D laboratory organizational types identified. In order to acquire this information, site visits to several research facilities in each of the environmental settings were undertaken.

For eight of the nine laboratory types, three to five case studies were selected for field study. In the case of Public Multi-Market laboratories, only two facilities were available for field study out of the four laboratories classified in that cell. The rationale for the selection of three to five cases is based on the logic provided by Arnold (1970) in his discussion of dimensional sampling. An investigation of three to five cases within taxonomically based classification schemes is seen as more than sufficient for drawing initial explanatory conclusions.

Thirty-two research facilities were visited. In each case, a common interview format was followed in a meeting with the laboratory directorate.[8] The objective of the field evaluations was to collect

background information regarding: 1) laboratory history, 2) organizational structure, 3) resource flows, 4) types of research conducted, 5) planning formats, and 6) research scope. Interviews with the laboratory directorate were followed up with laboratory tours and follow-up phone calls.

Case Study Review

The analysis of organizational difference centers on the subjective assessment of first-hand data regarding a set of organizations. In the case of this assessment, the set of organizational studies is composed of 32 cases selected from among the various cells of the R&D laboratory classification scheme. The demarcation is most important as it is differences between the organizations within a cell that should be noted. For instance, what is the degree of difference between laboratories producing generic products with varying levels of publicness? Do laboratories in each of the different environmental states have an identifiable set of characteristics that are indicative of general behavior? To answer these questions, an analysis of the case studies from each cell was conducted.

The analysis of each of the 32 cases used in this study is presented elsewhere (Crow, 1985) in much greater detail, along with a written case history. Here we have summarized the major characteristics for each laboratory, according to laboratory type. In addition, a shortened case study of a single laboratory of each type is presented as a means of highlighting the organizational characteristics which typify the laboratories in each classification. The organizational names

assigned each laboratory are fictional, but are indicative of organizational type.

Public Generic Laboratories (Cell I)

Public generic laboratories are characterized by their national focus and their utilization by the government as principal actors on the national research agenda. These laboratories, whether owned by the government, operated as a government owned/contractor operated research facility, or owned by an industry and financed by the government, are quite similar in both outlook and approach. Public generic laboratories are, for the most part, stable and, as a result, have gained a level of institutional status that makes these research organizations the key elements in the government's own research program. Public generic laboratories within their various organizational settings have many of the characteristics of the stereotypical government laboratory. For purposes of illustration we will review five public generic laboratory case studies. These cases are summarized in Table VII and include:

Acme Aviation Corporate Research Center: An industrially owned corporate level research facility of a major firm.

Energy Pollution Research Laboratory: A government-owned research facility operating as a part of a major science/technology related regulatory agency.

Institute for Advanced Energy Research: A single-program government-owned/contractor operated research laboratory. This laboratory has mixed ownership status and is operated for a government agency by a university.

Laser Science Center: This cooperatively owned and operated laboratory (government/university) is a single program research facility. The facility is operated as a government-owned/contractor-operated research laboratory.

The Neutron Institute: Cooperatively owned and operated, this laboratory is a part of a national research capability. A university operates this facility for the benefit of research, in general, with funding predominantly coming from proposals to the National Science Foundation.

A review of these cases indicates that there are two chief variations among the Public Generic labs. These variations include:

1) Government-owned and operated research facilities designed to support the implementation of specific policies.
2) Federalized research at various institutions that were either;
   a) ongoing and needed by the government, or
   b) needed by the government and federalized.

In both variations, the government, through its resources and processes, either actually controls the laboratory and all of its activities or permits the laboratories to operate as a part of a nongovernmental entity with government resources while pursuing the government's agenda. Regarding the second mode of operation, the government is interested in the continued delivery of the research products (knowledge, technology and personnel) which had generally been carried out by earlier laboratory forms over the long term. In each of these cases, the parent institutions, of their own volition and with their own resources, could not

have provided for the development and long-term maintenance of the laboratory while addressing a national research agenda.

The government supports each of the research facilities for its own interests. Those facilities with the highest levels of goal and structural influence from the government appear to have extreme difficulty in developing a high level of scientific expertise. The Energy Pollution Research Laboratory illustrates this point. In this case, the scientific program was not established outside of the government and then nationalized. On the contrary, the laboratory program was established to mirror the national policy objectives of the parent agency. Because of this fact, the laboratory itself never developed a core scientific capability. As could be expected, the parent experienced policy change quite often and, as a result, the focus of the research personnel changed in concert. Thus, rather than following the lead of scientific discovery, the laboratory staff attempts to search for technical alternatives to scientifically based policies. In this instance, policy is pushing the laboratories.

In the cases of the Acme Aviation Corporate Research Center, Institute for Advanced Energy Research, Laser Science Center and the Neutron Institute, the same type of interaction exists, but in two directions rather than one. To varying degrees, these laboratories push policy by providing new alternatives that were previously unavailable. For instance, the Acme Aviation Corporate Research Center, al*hough owned by an industrial organization, provides a mechanism for the government to induce one of its prime contractors to produce more advanced, energy efficient products. These more advanced products, although

generic in nature, eventually show up in the parent corporation's sales to the government in the form of new knowledge. In the government's cost-benefit calculation, this appears to be positive investment because it results in the development of new technological alternatives from which government policy can be implemented. The other laboratories similarly produce R&D products seen as important to the national interest.

With the exception of the Energy Pollution Research Laboratory, which is owned by the government, the remaining laboratories are all highly public facilities which came into existence during the period between 1940-1965 when government R&D support expanded rapidly. Even with the variation in impetus for formation, each of the Public Generic labs demonstrated similar structural and behavioral characteristics. These characteristics are reviewed below.

1) High levels of resource publicness do not necessarily imply that the Public Generic Laboratories are totally influenced by government authority. In fact, it appears that high levels of resource publicness provide the stability necessary to maintain unique organizational arrangements over the long term, which in turn provide for substantial goal independence in the setting of research agendas.
2) Public Generic laboratories produce largely at the technological and scientific frontiers. This production is largely in the form of publications and specialized technical services.
3) The focus of Public Generic labs is uniformly towards the long range with a particularly strong orientation toward national problems.

4) Public Generic labs are generally structured according to scientific discipline rather than government program or project constraints.

5) Public Generic laboratories have demonstrated remarkable stability, relatively speaking, in funding over the long term.

6) Program planning in both institutional planning and project funding are 'routinized' cyclical processes that occur on an annual basis under the auspices of the program plan. There is little competitive proposal preparation.

This characterization is general but applies best to the non-government-owned laboratories. Some modest contrast is provided by the Energy Pollution Research Laboratory which was not 'federalized' and moved into this environment. Instead, this facility was developed from several dispersed technical units from other, government owned, R&D laboratories. A careful review of the case study indicates that this laboratory is slightly different than the others in that it is more politicized and appears to exist in an environment of very high political authority influence. Regarding organizational stability, this Laboratory also varies to some extent as it is slightly less stable than the other four cases.

The Public Generic laboratories, while uniform in many characteristics, include two sub-categories. The government owned Energy Pollution Research Laboratory has a much higher level of government influence associated with its operation. This influence goes beyond the high publicness measure and includes high levels of governmental influence in resource acquisition, life cycle, goal setting, and structural functions.

Even with this difference, however, these laboratories are consistently similar in their research orientation, focus, and planning functions.

Public Generic laboratories are nationally oriented research facilities that have a long-range research focus and planning horizon. These laboratories perceive themselves as an important part of the national technology development process and play an active role in the policy development process.

Quasi-Public Generic Laboratories (Cell II)

The dominant characteristic of quasi-public generic laboratories is their tendency to "chase" government R&D opportunities. These laboratories have elaborate research marketing and research sales capabilities which are geared toward developing research and research services that the government appears to want. While the government is a principal client, these laboratories also market their research capability to industry and others. The four case studies summarized in Table VIII and listed below illustrate well this dominant characteristic.

Magnetic Science Center: Based at a university, this laboratory is funded by both government and industry. Government funding is an important variable to the survival of the laboratory.

California Cyclotron Center: This cooperatively owned research facility has evolved over the past 15 years to the stage where it serves both industry and government. This service research is generic in nature.

Energy Research Inc.: With its heritage in industry, this laboratory has evolved to the state where its ownership status is mixed.

Financed by both government and industry, this laboratory relies heavily on government funding for survival.

Institute for Solar System Development: Growing out of the research of a single university faculty member, this laboratory is a cooperatively owned research facility which is a part of a network of facilities supporting government and industry's solar energy research efforts.

Quasi-public generic laboratories sit at the fringe of the Public Generic facilities found in the Cell I environment. They vary significantly because of the fact that with the exception of the Institute for Solar System Development, there are no real research agendas. Rather, each of these laboratories offers its research services, specialized instrumentation and specialized personnel to any interested contracting group. It is through this 'piecemeal' research contracting that these facilities develop an ad hoc type of research program.

Because these laboratories have expertise to sell, but are operated independently of the government, they experience moderate amounts of goal influence from the government. This moderate level of governmental influence is exhibited through government management of projects, selection of research goals and as in the case of Energy Research Inc. the occasional designation of research personnel by agency personnel.

In all cases, Quasi-Public Generic laboratories actively pursue the marketing of their research capability to a broad range of potential customers. A primary customer of the past has been the government. To some extent, this fact has contributed to laboratory instability. Without continuing support that the laboratories must generate from govern-

ment and other contractors, not only does the laboratory suffer personnel shocks, but laboratory infrastructure also suffers.

Quasi-Public Generic laboratories, whether located at universities or private companies are organized around a particular set of skills or services. As time progresses and the need for those particular skills or services wanes, each of these laboratories have experienced substantial change, both structurally and behaviorally. These changes have resulted in redirections or massive reductions in the laboratories' efforts.

From the case studies of this laboratory type, it is possible to conclude the following:

1) Moderate levels of publicness and a generic R&D product result in a high rate of program change when not accompanied by either a guiding research plan or substantial parent organization support.
2) Moderate levels of publicness imply that the laboratory is not considered a part of the array of public facilities and as a result, is not a part of a routinized federal budgetary process. As a result, Quasi-Public Generic laboratories have developed extensive environmental scanning capabilities as a means of securing operating funds. These environmental scanning capabilities have resulted in these laboratories primarily working toward 'following' the research needs of both the government and industry.

3) Quasi-Public Generic laboratories appear to operate best in the general mode of independent semi-autonomous principal investigators.

4) Quasi-Public Generic laboratories appear to be relatively unstable and experience large fluctuations in their funding.

5) Research products are principally directed toward the achievement frontier and occasionally the technological frontier.

6) The research scope of Quasi-Public Generic laboratories is directed toward problems which are principally regional or local in scope.

7) Long-range planning is rare among this laboratory type. In general, the operations follow the long-range research plans of others.

8) Reductions in federal support result in either program cutbacks or movement toward more locally oriented industrially supported research.

9) The elimination of federal support of these facilities would in all likelihood result in their immediate demise.

10) The research focus of Quasi-Public Generic laboratories is as broad as the market.

Quasi-Public Generic laboratories are essentially research businesses directed toward the production of generic products, predominantly for the government. In general, they do not have a self-determined, coordinated research agenda. Instead, these laboratories have loosely coordinated research thrusts in areas which the government is interested enough to support. Because of the extent of government investment in

research ideas and services of these laboratories, their level of governmental influence is relatively high.

Because Quasi-Public Generic laboratories must "sell" their research on an idea basis, these laboratories tend to follow national trends rather than set them. Because of the constant fluctuations in the research market, the stability of these laboratories is limited. This fact contributes to a sense of competitiveness that was not seen in the Public Generic laboratories.

Independent Generic Laboratories (Cell III)

The hallmark of the independent generic laboratory is diversity and independence. These laboratories operate in environments with both the lowest level of publicness and the lowest level of market influence. As a result, these laboratories are individually unique and follow their own, albiet narrow, research agenda. Independent generic laboratories are the only research laboratory type free to chart its own course, with little concern for the government or the market. As might be expected, however, these laboratories suffer from funding difficulties. Three cases highlighting these characteristics are reviewed (see Table IX) for summary), including:

Chemical Processing Institute (CPI): Directed toward the long-term research needs of a particular industry, this cooperatively owned research laboratory is operated by a university.

The Indiana Institute (II): This privately founded research facility is cooperatively operated with funds from private, industrial and government sources.

Center for Advanced Energy Physics (CAEP): Organized around the research efforts of an academic department, this laboratory is cooperatively owned.

Independent Generic laboratories are highly independent research organizations, with non-governmental base support. Generally, the base support is in the form of personnel costs and/or facilities. In each case, the base support is considered to be the means through which a laboratory will develop. At both the Chemical Processing Institute and the Indiana Institute, an articulated research agenda and an active directorate, programs have developed. In the case of the Center for Advanced Energy Physics, no organized effort has been undertaken and as a result, the laboratory, although as equally endowed from the start as either of the other cases, has not been able to reach the critical state necessary for productive research operations.

Operating from their research base, each of the Independent Generic laboratories has as a principal function the creation of an environment conducive to research. It is the intent of each laboratory to create an environment from which individual scientists/engineers can pursue their own research agendas. The pursuit of these research agendas includes the requirement that individual researchers acquire much of their own research support. The laboratories in this mode provide an organizational umbrella for these pursuits. In addition, in the case of the Chemical Processing Institute and the Indiana Institute, the laboratory provides a program focus and overall capability. In these cases, the program focus is well-planned and enables the individual researcher to

become integrated into a larger scientific group pursuing a particular problem area.

Independent Generic laboratories pursue their own research agendas and are not a part of larger federalized systems. In the cases of CPI and the Indiana Institute, the development of the laboratories was a function of a desire to produce new types of organizational forms for research. In the case of the Center for Advanced Energy Physics, the initial intent was similar, but the realization of the goal has yet to come about.

Specific conclusions regarding Independent Generic laboratories include:

1) Independent Generic laboratories were conceived and initiated outside of the realm of the federal government or specific industrial owners.
2) Independent generic laboratories operate from a base of support and attempt to pursue contract research from this base.
3) The research products of independent generic laboratories are predominantly directed toward the technological and scientific frontier.
4) The general research focus of independent generic labs is narrow, involving in general only one or two research topics.
5) Independent Generic laboratories have a long-range focus in a narrow technological area.
6) Funding for this laboratory type is relatively stable, but in all cases is less than desired and, therefore, results in an unstable environment.

7) The organizational structure of these labs is one of autonomous principal investigators.

8) Independent Generic laboratories are insulated from policy and market fluctuations.

9) Research planning is done on an annual to biannual basis.

These conclusions indicate that Independent Generic laboratories operate outside the "mainstream" of U.S. research. These laboratories are influenced minimally by the government and minimally by the market and as a result they have established research agendas keyed almost exclusively to the expertise of their staffs. These research agendas are only minimally coordinated within the laboratories themselves. These laboratories are aptly characterized as self-directed research homes for research professionals. This characterization implies that these laboratories exist in their own worlds and set their own courses.

Because of relatively lower funding levels, these laboratories, while stable, have a narrowly focused research agenda. This research is nationally oriented but unlike Public Generic laboratories, the research is limited to a narrow technological area. Work in new technological areas develops slowly as a function of increases in funding and the acquisition of new personnel. In sum, Independent Generic labs appear to be the environmental setting of an independent type of research laboratory with a national orientation in a narrow technological focus.

Public Multi-Market Laboratories (Cell IV)

As the name implies, Public Multi-Market Laboratories are government financed research facilities producing an R&D product with various levels of market influence. As a result of this variable level of

market influence, these laboratories are characterized by complex research agenda-setting and, when compared to Public Generic laboratories, an inordinate level of organizational instability. These research organizations, as summarized in Table X, appear to be in a constant state of flux. We observed only four laboratories in this environment and were able to conduct case study analysis on only the two laboratories listed below.

The State Energy Lab: This state government-owned and operated laboratory is focused toward a broad mission of natural resource related research.

The Atomic Energy Laboratory: This government-owned laboratory is operated under charter with a government corporation. The researchfacility is directed toward nuclear research.

Even with the limitation of this analysis, there are some important characteristics common to the two cases studied. Both the State Energy Lab and the Atomic Energy Laboratory operate under the general auspices of a governmental agency to deliver technology or technical services, which at least at the time of inception, could not be provided by the market. The State Energy Lab produces technical services required for state energy resource development and the Atomic Energy Laboratory produces technology in an area where the government holds monopoly rights over the field of development. In both cases, the laboratories were established to meet the special needs of the general public. These needs included both generic and proprietary research products, thus the multi-market designation.

Specific conclusions regarding Public Multi-Market laboratories include:

1) Public Multi-Market environmental conditions create, over the long term, difficult operating modes for laboratories. There are many competing goals with strong government influence.
2) Structurally, Public Multi-Market laboratories are departmental.
3) This laboratory type operates predominantly on the technological frontier.
4) Research planning among Public Multi-Market labs is biannual to annual in nature.
5) Organizationally, Public Multi-Market laboratories appear unstable; they are pushed and pulled by the government to juggle among competing goals.
6) The research scope is regional or intrafirm.
7) The research focus is short to mid-range.
8) Public Multi-Market laboratories are highly politicized. By politicized, it is implied that senior managers are quite responsive to policy shifts.

This laboratory environment appears to be a relatively harsh operating setting in terms of stability, politicization, and difficulties in goal setting. The laboratories observed in this cell exist to serve both the market and the government with all or much of their funding being received from the government. In addition to high government funding, these laboratories experience high levels of governmental influence with regard to most of their basic organizational variables. This influence appears to be exerted as a mechanism of control because

of the partial market orientation of the R&D product. Conversely, market influence dictates performance schedules and routines from these laboratories that because of the strong influence from the market and the government with all or much of their funding being received from the government. In addition to high government funding, these laboratories experience high levels of governmental influence with regard to most of their basic organizational variables. This influence appears to be exerted as a mechanism of control because of the partial market orientation of the R&D product. Conversely, market influence dictates performance schedules and routines from these laboratories that because of the strong influence from the government commonly results in organizational conflict. Public Multi-Market laboratories appear to attempt to be all things to everyone in terms of product, yet are heavily constrained by heavy governmental influence.

Quasi-Public Multi-Market Laboratories (Cell V)

High technology and big science characterize the Quasi-Public/ Multi-Market laboratory. These are the 'think tank' research laboratories which are relied on by both government and industry for new ideas and practical market applications. With independent research agendas and highly competent staffs, these laboratories are called upon to address either a wide range of national problems in the case of the larger labs or a narrow range of national problems for the smaller versions. The three cases reviewed in Table XI exemplify these characteristics. These cases include:

The Magnetic Transport Center: This government-chartered, university-operated, multi-source funded research facility serves a number of research clients. As a result, it is cooperatively owned.

General Energy Inc.: This industrially owned laboratory is totally financed through government funds as well as its own profits from government research. In addition, it acquires research support from other industrial groups.

Institute of Superconductivity: This cooperatively operated laboratory is based at a major university with research funding from a number of sources.

Quasi-Public Multi-Market laboratories are best characterized as very specialized research facilities which are designed to meet particular needs of both industry and government. The laboratories evaluated as a part of the case study process are largely autonomous in setting goals regardless of ownership and base funding from both government and industry. This goal autonomy is based on the fact that each of these research facilities has a self-determined research agenda and through the marketing of research ideas to a number of sponsors, a laboratory program is established.

General Energy Inc. is substantially larger than either the Magnetic Transport Center or the Institute of Superconductivity, yet when it is considered as a set of research divisions, there are a number of similarities. The characteristics of the two smaller laboratories are similar to the division of General Energy Inc. in that they all operate from a base support level coming from government or industry with additional funding coming from shorter term or single project

contracts. In fact, the similarities are so great that both of the smaller labs could easily be groups within the General Energy Inc. laboratory.

Each of the Quasi-Public/Multi-Market research facilities exists at the fringe of the federal array of research labs. This position places each of these facilities outside of the day-to-day policy process and as a result produces very independent thought. Government comes to these laboratories not to conduct project X or Y, but participates in the self-determined programs of these laboratories because it is of potential benefit. Quasi-Public/Multi-Marked laboratories are in the business of producing and selling self-determined research programs, not projects. This fact, although on the surface similar to the Quasi-Public Generic laboratories in Cell II, is different because of the way in which these laboratories establish their own agenda. Quasi-Public Generic Laboratories sell research projects (not programs) and services to the government to meet particular needs. Quasi-Public/ Multi-Market Laboratories, while they do some of that, have as their predominant goal either the conduct of research for the development of specific new technologies. These facilities exist to conduct comprehensive research programs towards that end, rather than a series of disjointed projects as was the case among the Quasi-Public Generic laboratories.

The Quasi-Public character of these research facilities has several effects on laboratory behavior. In the case of General Energy Inc., the intent of the laboratory is to develop new advanced energy technologies including marketable products that are to be distributed by subsidiaries of the laboratory or the parent industry. While the government may have

similar interests, it remains distant and funds General Energy Inc. to be a part of what they are doing. Similarly, the Institute of Superconductivity is in the "business of operating a research program" and if contractors want to participate that is fine, but not critical. The Magnetic Transport Center was created to address particular problems through a unique organizational arrangement not already available in the federalized system. In each case, the laboratories are an important part of their respective national research pools, but have been kept below the higher levels of governmetal influence common in Cell I for reasons of interest from both the government and the laboratories.

Quasi-Public/Multi-Market laboratories serve both industry and government through the marketing of research programs that meet national needs. These programs require substantial continuous support and independence to be successful. Each of the cases have demonstrated that long-term delivery of useful research products to both industry and government is possible without becoming a part of either system.

Specific conclusions regarding the Quasi-Public/Multi-Market laboratories include:

1) The environment is characterized by moderate levels of publicness and balanced R&D product result in laboratory operations that are independent research entities which are, while a part of the "national research resource," self-determinant in their goals and mission.
2) Quasi-Public/Multi-Market laboratories have a national focus and orientation.

3) Long-range planning and the development of research program plans are common.

4) Federal support, while important to program stability, is not essential for laboratory survival.

5) Quasi-Public/Multi-Market Laboratories consider themselves independent of the federal bureaucracy and as a result, capable of objective non-policy directed research.

6) Research is directed toward the technological and scientific frontiers.

7) Research investigators operate predominantly in the research group mode. While independent autonomous investigators do exist, such status is gained only after attaining scientific or technological eminence.

8) Laboratory planning is on an annual to semi-annual basis.

Quasi-Public/Multi-Market laboratories were the most unusuallaboratory type observed as a part of this analysis. These laboratories, at first glance, appear to have many of the same orientations of Public Generic laboratories in Cell I; they are nationally oriented facilities with research directed toward the scientific and technological frontiers. However, these laboratories are quite different. Their research agendas, while influenced by national policy, are largely self-determined. The laboratories have developed their own mechanisms for determining their research agendas. These research agendas, probably because of internal mechanisms that lead to their establishment, are financed by a diverse group of governmental and industrial sources. As a result, these laboratories are influenced by both the market and the

government in terms of authority inputs as well as the direction of the R&D product. Subsequently, the environmental setting appears relatively stable, particularly for the older laboratories.

Independent Multi-Market Laboratories (Cell VI)

Pushed by the market of the parent industry, the Independent Multi-Market Laboratory is characterized by organizational instability, frustration, and often confusion. These research organizations want to produce non-market, often basic research products, but appear to be bound by the constraints of the market orientation of their parent organizations. In simple terms, these laboratories want to have it both ways. On the one hand they want to be able to act and behave in a fashion similar to the Quasi-Public/Multi-Market laboratories, but at the same time they have an aversion to too much government financing. The four cases reviewed in Table XII illustrate this conclusion. These cases include:

Ewing Oil R&D Inc.: An industrially owned laboratory in the oil industry with both proprietary and generic R&D products.

Petro Chem Labs Inc.: An industrially owned laboratory in the petrochemicals industry with proprietary and generic R&D products.

Seattle Tech Inc.: Growing out of the collaborative action of two firms and a government agency, this facility is presently industrially owned.

Minerals Research Laboratories Inc.: An outgrowth of a consulting/research business, this laboratory serves the minerals industry as a contract research facility.

Independent Multi-Market laboratories produce both generic and proprietary research products in an environmental setting with little or no

57-279 O - 87 - 27

direct influence from the government. This lack of direct influence from the government has resulted in a set of laboratories which are heavily influenced by changes in the economy. While each of the Independent Multi-Market laboratories produce both types of R&D products, downturns in the markets of the laboratories' income sources result in movement toward proprietary research. Upturns in market conditions conversely result in movements toward generic research. Thus, this laboratory type experiences changing research objectives on a regular basis.

In each of the cases in this cell, laboratory development was initiated for the purpose of providing technical service to either an industrial sector or individual industrial firm. This does not imply, however, that these laboratory organizations are industrially owned. As the capability to provide technical services advanced through the addition of research personnel and equipment, longer-range research was typically undertaken during periods of economic prosperity. During other periods, each of the cases reviewed in this cell reverted to their original technical service roles.

Two of the laboratories (Ewing Oil R&D Inc. and Mineral Research Laboratories Inc.) have pursued governmental funding to supplement their research income during economic downturns. In both cases, the projects were of short duration and were at best temporary activities intended to maintain or develop longer-range research capabilities.

Without exception, each of the Independent Multi-Market laboratories is interested in pursuing long-range research. Without exception, the process of establishing and maintaining such an interest and

capability has not been easy. The daily technical service needs of the firm or firms served by these laboratories, and the occasional emergency situations brought on by economic downturn all interact to make the development of a long-range research effort difficult. Only Petro Chem Labs, Inc. (PCL) has succeeded in the systematic development of a long-range research function. This occurred only after careful planning and gradual growth. At the same time, a market decline in the product lines of PCL's parent corporation could, according to laboratory management, easily cause this program to be reduced.

Specific conclusions from the Independent Multi-Market case studies include:

1) Laboratories with low levels of resource publicness and a balanced R&D product are heavily influenced by market changes.
2) Independent Multi-Market Laboratories have long-range applied research goals, but are often forced as a result of economic downturns to focus solely on the achievement frontier.
3) Independent Multi-Market laboratories have an industry specific focus which is short to mid-range in orientation.
4) Laboratory structures are departmental with most of the research organization dedicated to technical service oriented research.
5) Research program planning is market directed. As a result, as the market experiences stress, the research plan is immediately rejected for an ad hoc plan.
6) Independent multi-market laboratories experience program shifts and budget reductions with some frequency, implying that their research environment is not stable.

7) The research focus of independent multi-market labs is predominantly toward the achievement frontier with some research on the technological frontier during periods of economic prosperity.

8) Federal support appears to be of little consequence to independent multi-market labs.

9) The principal investigators are generally not autonomous.

These conclusions indicate that Independent Multi-Market laboratories operate as a function of the current market conditions affecting either the parent firm or the client industry which the laboratory serves. Unlike the Independent Market laboratories in Cell IX that appear to be more stable, particularly with regard to market fluctuations, these laboratories appear to focus on technical service-related research. This does not imply that technical service research is not done in Independent Market laboratories or other laboratory types because it is the difference with this laboratory type is a matter of focus.

Largely due to the conflict between multiple R&D product goals of the laboratories and the narrow goals of the parent industries, these laboratories consistently are pulled away from their generic R&D thrusts during periods of market instability. While the rationale behind this somewhat confusing behavior remains unclear, let us suggest the following. Independent Multi-Market laboratories, like Public Multi-Market laboratories, exist in a complex and often confusing environment in which they are heavily influenced by the parent organization(s) from which they receive their funding. They are also influenced by non-market factors as a result of their desire to produce generic R&D

products. Because of this conflict, Independent Multi-Market laboratories are less stable than the similarly directed Independent Market laboratories. As a result of their unstable research environment, these laboratories are more intensely affected by market shifts which require constant redirection of effort. As a result, these laboratories have a limited research horizon and are focused on the achievement frontier.

Public Market Laboratories (Cell VII)

Public Market laboratories are government-financed industrial research institutes of the European tradition. Similar to the industrialized nations of Europe, various units of governments in the US and Canada have financed and in some cases staffed research facilities for the sole function of conducting a research program for the consumption of a specific industry or ministry. In both cases, the research results are proprietary and the research funding base is highly public. The resulting organizational conflicts are illustrated by the four cases detailed in Table XIII and listed below.

Southwest Mining Laboratory: This government-owned and operated laboratory serves both regional and national mining interests through the production of market-oriented research.

The Provincial Mining Laboratory: Owned and operated by an agency of government at the regional level, this laboratory serves as the research arm for a regionally-based, multi-firm, mining industry.

Advanced Propulsion Laboratory: Owned and operated by a governmental agency on a University campus this laboratory serves the parent agency through the production of research which is solely consumed internal to that agency.

Underwater Energy Systems Center: Cooperatively operated by a major university and a government agency, this laboratory is charged with producing a proprietary product for the agency.

Unlike the Public Generic laboratories which are funded through relatively stable program funding, Public Market laboratories are funded on a project basis. Even those laboratories operating under the general auspices of a governmental agency are funded on a project basis. This lack of base or long-term support has contributed to an unstable funding pattern in three of the four cases reviewed. In addition, the lack of stability in the general operations of the Southwest Mining Laboratory, the Provincial Mining Laboratory, and the Advanced Propulsion Laboratory can be attributed to a general lack of long-range planning or long-term commitment on the part of the laboratories themselves or on the parent organizations.

The most dominant characteristic of the Public Market laboratories is the fact that they are so easily influenced by policy and market changes. Both laboratories, the Southwest Mining Laboratory and the Provincial Mining Laboratory, which are connected with the minerals industry through the delivery of technical services to that industry, were targeted for shutdown in the early 1980s. These shutdowns were the result of changes in the target industries' markets as well as changes in the parent agencies policies in response to these market changes. In response, the Southwest Mining lab reacted politically and secured an operating budget sufficient to maintain the laboratory. The Provincial Mining Laboratory, on the other hand, totally revised its research mission from mid- to long-range research to short-range research. In

both cases, the laboratories experienced extensive reorientation of personnel and a complete rethinking of goals and objectives.

In each case, Public Market laboratories are closely affiliated with a larger governmental organization. Regardless of ownership, each of the laboratories pursues a research program which is supported in piece-meal fashion, generally from a series of proposals.

Historical analysis of the funding of these laboratories indicates that although funding is large, its growth is sporadic and subject to rapid decline. In addition, much of the funding base of these laboratories is directed toward routine technical service and support functions. The laboratories, as a part of the larger governmental research organization, are all well integrated into the policy process of the parent agency. Each of the laboratories reviewed conducts research which is mandated and selected by the parent agency. In this mode of operation, each of the laboratories responds to the changing policies of the parent agency through new research proposals. It is fair to say that each of the laboratories spends a good deal of its organizational energy in reacting to changing policies and directives while at the same time adjusting to market conditions related to the research project. An example is the Advanced Propulsion Laboratory and its pursuit of research based on direct Congressional mandate and divergent parent agency input.

Because of the strong orientation toward the production of proprietary R&D products, Public Market laboratories also experience market-related political vulnerability. The two mining laboratories, operating

as service laboratories for the regional minerals industry, became politically vulnerable during market declines. The Advanced Propulsion Lab and the Underwater Energy Systems Center, both producing proprietary products for public sector consumers also experienced certain political vulnerabilities. This is illustrated by the case of the Advanced Propulsion Laboratory. The research product marketplace for this laboratory was controlled by managers not interested in the product. As a result, both the type of research requested and the products produced were deemed inadequate. Because of this inadequacy, the laboratory was vulnerable to shutdown. In this case, however, the laboratory was able to overcome this market impact through interdiction by Congressional subcommittee.

Specific conclusions regarding Public Market laboratories include:

1) Environments with high levels of publicness and proprietary R&D products result in highly politicized laboratories with relatively unstable programs and funding.
2) Research is conducted predominantly on the achievement frontier and during periods of stability, the technological frontier.
3) Research objectives tend to be short-range.
4) Research planning in Cell VII laboratories is highly influenced by the parent agencies and their changing policies.
5) Research planning horizons are typically one year and at best three years.
6) Laboratory funding is on a project basis with project selection largely resulting from intra-agency review.

7) Public Market laboratories are, in general, highly politicized with laboratory researchers often in direct politico/technical contact with parent agency personnel and legislative personnel.

8) Public Market laboratories are in general less stable than other high publicness laboratories.

9) Public Market laboratories are generally structured in classical hierarchical arrangements designed to meet the current needs of the parent agency.

The discussion above depicts a laboratory type that is unstable, highly politicized, and subject to severe environmental conflict. In this environment are laboratories either owned or directed by the government that are attempting to produce a market-directed research product for a specific industry. Such an environment appears to be subject to conflict and unstable R&D organizations result. This instability and its effects are particularly obvious when compared with the other high publicness laboratories. Their environments are more stable and as a result there is a broader research agenda, broader focus, and an orientation toward research rather than technical service.

Public Market laboratories seem to have fallen victim to a complex environment. As a result, these organizations spend a good deal of their time reacting to political authority influences and changes. Such a reactive mode of operation results in poor moral and possibly in poor overall effectiveness.

Quasi-Public Market Laboratories (Cell VIII)

The Quasi-Public Market laboratory is a government-financed market development center. In these research organizations we see the shared financing of product development and research service activities. For a number of reasons, these laboratories rely on government financing as a means of developing products for general market consumption. The three cases reviewed in Table XIV show a tendency to produce new products for the marketplace with a substantial amount of direct government support. These cases include:

Energy Engineering Inc.: An industrially owned research laboratory that grew up as a technology spin-off from a major research university. The laboratory relies heavily on government financing, but is financed from a range of sources.

Regional Energy Research Center: This laboratory has mixed ownership status. Housed at a university, the laboratory is a government-chartered organization with funding from a number of sources.

Advanced Turbine Research Center: This industrially owned laboratory is directed toward the production of a market-oriented research product. The development of this product is funded according to stage of development by either the parent corporation or the government.

Quasi-Public Market laboratories might at first glance appear to be quite dissimilar. Of the three cases reviewed, there is a divisional laboratory of a major corporation (Advanced Turbine Research Center), a privately held high technology firm (Energy Engineering Inc.) and an industrial research and technical service institute at a university (Regional Energy Research Center). A close analysis of each of these

facilities reveals that in all cases government financing is critical to the development or delivery of a proprietary R&D product. In the case of the Advanced Turbine Research Center, the parent corporation has the potential to make a profit from the laboratory's R&D product, yet requires substantial government investment for the laboratory's operation. Likewise, Energy Engineering Inc., although a part of a privately held high technology firm, requires its entire R&D operation to be externally funded, largely by the government. Finally, the Regional Energy Research Center, although well below a critical mass level, required government funding initially and government contracts now for even short-term delivery of proprietary products for the betterment of local energy related industries.

In each of the Quasi-Public Market laboratory cases, the operations are strongly influenced by the government as well as the market. The market influence, however, is reduced as a result of the moderate levels of publicness. Each of the laboratories enjoys lower levels of organizational risk as a result of the government's financing of between 26% and 75% of the R&D effort.

Specifically, the conclusions regarding Quasi-Public Market laboratories include:

1) The environment includes moderate levels of resource publicness and a proprietary R&D product contains R&D organizations in need of substantial external R&D support for their product or service development activities.
2) Structurally organized as departments around the technology produced or technical service delivered.

3) Research is generally single technology-focused.

4) Quasi Public Market laboratories operate largely on the achievement frontier with occasional efforts on the technological frontier.

5) Research planning in Quasi-Public Market laboratories is not common and, when present, is on a no longer than annual time frame.

6) Quasi-Public Market laboratories tend toward instability. As they are at least partially funded by sources other than the parent, the laboratory must generate much of its own operating capital on at least an annual basis.

The research focus is narrow and when geographic is regional.

8) Funding processes involve competitive proposal preparation and external review.

9) Goal setting is the result of a goal concurrence effort undertaken by the laboratory. Each laboratory attempts to find external support both in the government and among the proprietary R&D product consumers. To say the least, it is a complicated process.

As producers of market-directed R&D products, Quasi-Public Market laboratories have a single output influence. Input influences, however, are more complex with 25 percent to 75 percent of the laboratories' budgets being financed by the government. With this level of government influence, these laboratories suffer from the same type of influence conflict as was observed among Public Market laboratories but to a lesser extent.

While the influence conflict experienced among these laboratories is less than in the Public Market type, the funding stability is probably almost as poor. Because these laboratories are not funded automatically by either a parent or the government, there is always a fund chasing obstacle course that must be run. While this course is substantially less difficult than experienced by Quasi-Public Generic laboratories, it does contribute to some instability among these laboratories.

The market orientation of the R&D product of these laboratories makes them subject to the fluctuations of the market. This effect, however, is much less than in the Independent Multi-Market environment. This is attributed to the increased level of publicness.

This laboratory type tends to be single technology-focused and does not have the national orientation of Public Generic and Quasi-Public/ Multi-Market laboratories. As a result, these laboratories are not major actors in the R&D policy arena. They are, however, producers of advanced products and processes for either government or private markets.

Independent Market Laboratories (Cell IX)

Independent Market laboratories are the archetypical industrial R&D laboratories. These laboratories are market-directed research facilities with the little or no influence from the government. They serve the firm(s) of which they are a part and behave in the way industrial R&D labs are generally assumed to behave -- that is, they develop proprietary products and processes with their own resources. Four examples of Independent Market laboratories are reviewed in Table XV. These laboratories include:

Power Systems Laboratory Inc.: This industrially owned energy research facility is funded largely by the parent corporation as well as the principal consumers of the firm's products.

Smith Chemical Research Laboratory: Industrially owned chemical laboratory of a major corporation.

Black Forest Energy Laboratory Inc.: Industrially owned paper and pulp laboratory serving the regional technology needs (particularly energy related research) of a major corporation.

Metalville Research Center: Industrially owned energy/materials research laboratory serving a major corporation.

Although not always owned solely by an industrial concern, these laboratories are dedicated to the conduct of research and the delivery of technical services for the benefit of a market-driven parent organization. These laboratories conduct research programs intended to enhance processes and products, as well as search for new technological alternatives during strong economic periods. In each of the laboratories reviewed, the role of the government was minimal. The extent of government influence was limited to the indirect influences resulting from procurement or regulatory policies.

In all of the cases reviewed, the laboratories served the operating units of the parent organizations first and foremost. Research was directed toward improving daily operations of facilities or assisting customers with technical problems regarding the parent organization's processes or products.

Laboratory resources were, depending on the age of the laboratory and the extent of the research tradition in the parent organization,

available for longer-range research. This research, however, was almost always directed toward new proprietary technology. Each of three laboratories which had recognized long-range research efforts (Power Systems Lab, Smith Chemical Lab and the Metalville Research Center) had unique organization and funding arrangements for these efforts. In all cases, however, they were coordinated with extensive input from the leadership hierarchy of the parent organization.

Research directed toward the needs of the operating units or customers of the parent organization were in every case strongly influenced and, in some cases, directed by the operating units and the marketing staffs. As a result, the focus of much of the research in each case was toward problems on the achievement frontier. In these cases, environmental stress in the market or in the operating units of the parent organization resulted in a shifting of laboratory focus on the problem area. While age of the laboratory appeared to reduce the impact of these environmentally induced changes, they existed in each case.

Specific conclusions regarding the Independent Market laboratories include:

1) Independent Market labs are focused largely on assisting the operating divisions of the parent organization with incremental improvements in process or product.
2) Independent Market laboratories are market-directed with much of their research directed toward serving the technical needs of individual customers, in a sense customizing the process or products of the parent organization to meet particular needs.

3) Research is directed primarily toward the achievement frontier. With age and financial stability, the laboratories do pursue, although on a small scale, longer-range applied research. The conduct of basic research was not observed.

4) Research planning for most of the activities is coordinated with the marketing and/or operating divisions of the parent organization. For the most part, these planning efforts are short-range in scope. Regarding longer- range research, parent organization leadership along with laboratory management plan on a longer research horizon for a few specific projects.

5) Structurally, Independent Market laboratories are organized to serve the needs of the parent organization through topical research divisions.

6) The research focus of these laboratories is relatively narrow as it is limited to the market arena in which the parent organization operates.

7) Organizational stability is quite high.

8) Independent Market laboratories are well integrated with the external research community.

9) External review of R&D activities is very limited.

While many of these laboratories in the questionnaire return were cooperatively rather than industrially owned, the fact remains that these laboratories exhibit the characteristics of the industrial laboratory stereotype. Research is an important function of the parent's organization plan and these laboratories have been chartered and funded to meet this need. These laboratories serve to produce new processes/

products and to meet the technical needs of clients of the parent. They are stable, well funded and do not exhibit massive changes with the market. This fact, however, is probably a function of the fact that only healthy laboratories were studied from this cell. Research among the laboratories is generally directed toward the achievement frontier, but discretionary support for 'good ideas' was also available. In general, these laboratories are archetypal of the industrial laboratory so often referred to in the technical change literature.

Summary of Case Study Findings

The case studies reviewed above indicate that there are distinctly different characteristics among the various laboratory types. For instance, comparative analysis of Public Generic and Quasi- Public Generic laboratories indicates that a reduction of publicness levels among laboratories producing a generic product leads to a reduction in stability, shorter planning horizons, and a more applied research product. While it cannot be said with certainty that a reduction in publicness levels would produce these behavioral changes, it can be hypothesized that laboratories producing generic R&D products in an environment of high publicness versus an environment of moderate publicness are more stable, focus more on long-range research, and have longer research planning horizons.

Table XVI summarizes the variation and general organizational characteristics of the various types of R&D laboratories classified. These differences are at least the partial result of the aggregate environmental impact of varying combinations of government influence

(publicness) and market influence (nature of R&D product). These differences, when analyzed as a function of the explanatory variables of the taxonomy, result in a number of conclusions regarding both the characteristics/expectations of the laboratories and the potential reasons for some of the differences.

With the assumption that laboratory organizations are a function of their environment, the classification of laboratories based on that environment can successfully separate laboratories. It is also assumed that the same variables can be used to at least partially explain the differences observed. Given these assumptions, the major differences between R&D laboratory types summarized are reviewed below.

--Table XVI about here--

Research Scope

Variation in research scope (target of research product and orientation of research program) is limited. Only Public Generic laboratories and Quasi-Public Multi-Market laboratories have a national or interfirm research scope. In each of the other environments, laboratories operate, due to a number of constraints, on a research agenda largely directed to the larger needs of the parent organization(s). By this it is implied that the effects of the environment on laboratories in the remaining seven cells precludes operationalization of a broad research scope.

Public Generic laboratories, because of their national orientation, stable funding and minimal market influences, have been able to operate

on the scientific and technological frontier. Quasi-Public/Multi-Market laboratories, on the other hand, set their own agenda and have developed national/interfirm-oriented research programs on their own. These research agendas are not set by national policy, but are determined by the laboratories themselves. This environment of balanced R&D products (directed toward both markets) and moderate publicness appears to permit sufficient stability for this type of laboratory. This laboratory type, while not dominantly influenced by the government or the market, is able to maintain a self-identity and determine its own research scope.

Laboratories in each of the remaining seven cells have a somewhat narrower scope of research, as prescribed by the environmental setting. For instance, the research scope of the Quasi-Public Generic laboratories is substantially narrower than the Public-Generic laboratories, even though they both produce a generic research product. The reason for this narrowing in research scope in the Quasi-Public Generic laboratories is a function of the fact that these laboratories have insufficient recurring resource levels to insure stability over the long term. As a result, these laboratories follow federal funding patterns. This process reduces research scope because individual grant or contract awards are generally of a non-national/interfirm nature. Since these are what is pursued, these laboratories are prevented from operating with a national research scope.

Type of Technical Change

Both Public Generic and Quasi-Public/Multi-Market laboratories pursue self-determined research programs. As a result, they are less directed toward local/neutral (evolutionary) type changes.[7] While the

high publicness level experienced by Public Generic laboratories precludes total independence, it is important to note that these laboratories were, for the most part, federalized because of their independent ongoing research programs. The government desired a movement away from the changeable technical focus approach found in most industries. The desire was for discontinuous (evolutionary) change.

Laboratories in the remaining cells are prescribed by their environment to focus on advancing knowledge only in a linear fashion (local-neutral technical change). In Independent Multi-Market laboratories, this environmental constraint is best illustrated. The fact that they rely almost totally on parent organization funding means that first and foremost their research is directed toward linear improvement of existing products/processes. During those periods when nonlinear technical alternatives can be pursued, there is always the environmental reality of focusing on solely the parent organization's problems.

Research Frontier

The research frontier of each type of laboratory varies as a direct function of environment, but in a complicated sense. As might be expected, not all of the laboratory types producing a generic R&D product direct their research toward the scientific and technological frontier. Quasi-Public Generic laboratories direct their research efforts toward the achievement and technological frontiers because of the lack of full integration in the national array of Public Generic research laboratories. The trend between the laboratory types is hypothesized to be as follows:

1) Among the laboratory types producing a generic R&D product, high publicness implies orientation toward the scientific frontier. As market influence increases the orientation moves towards the achievement frontier.

2) With the exception of the Independent Market laboratories, R&D product as it moves toward generic implies movement away from the achievement frontier.

3) Laboratory types directed toward the achievement frontier, at least in part (Cells II, VI, VII, VIII and XI), are heavily influenced by the market. In addition, all of these laboratory types, except Independent Market laboratories, are organizationally unstable.

Research Planning

Four basic variations regarding research planning occur among the nine types of R&D laboratories identified. Public Generic laboratories are unique in that their planning horizons are generally greater than three years. The longer horizons are a function of the high levels of publicness and the fact that a generic R&D product is produced.

High publicness environments result in longer-range and more formalized planning. This tendency is intensified as the R&D product becomes more generic. Environments with lower levels of publicness plan generally only on an annual basis and even then are subject to rapid, market-induced changes in plans in the Independent Multi-Market and Quasi-Public Market laboratories.

Organizational Stability

The stability of a laboratory organization is a function of the number and extent of budget fluctuations, program change, and life cycle threats. Given this definition, stability is a function of high publicness in generic laboratories, low publicness in proprietary (market directed) laboratories and moderate publicness among those mixed market labs. In other words, laboratory stability appears to come with a clear mission and single funding source as in the cases of Public Generic and Independent Market laboratories or a self-determined course with balanced products and funding as illustrated by the Quasi-Public/Multi-Market laboratories. Another consistent difference was the program versus project-centered funding in the laboratory environments exhibiting organizational stability.

Organizational Structure

The impact of the market (R&D product) is the key determinant affecting the structure of the R&D laboratory. The more proprietary the product, the more departmental the organizational structure. Laboratory types tending toward a generic R&D product are organized around the principal investigator-centered research group. In these cases, the principal investigators have varying degrees of autonomy. Nonetheless, the research is organized around this type of research group.

Core Hypotheses

While the case study data do not permit us to make definitive conclusions about laboratory behavior, tentative findings suggest that this supplement to the traditional dichotomous distinction between public and private laboratories has some value.

The findings presented here encourage us to suggest the following core hypotheses about laboratory behavior:

1) The production of generic research in a stable environment requires high levels of publicness.
2) Moderate levels of publicness in either the production of generic or proprietary research products produce a laboratory type which is highly unstable and in some respects below an optimum threshold. This instability is the result of high levels of environmentally based goal conflict in the organization.
3) Higher levels of publicness result in longer-range planning horizons.
4) Proprietary R&D environments result in very short planning horizons and a constant need to "re-plan" research programs during their implementation due to market changes.
5) There is no relationship between pubicness and research scope to address national or interfirm needs.
6) Level of publicness is not the determinant regarding organization structure. Organization structure is largely a function of market influence. The more generic the R&D product, the more decentralized the structure and the more proprietary the product, the more centralized the structure.

R&D Policy Implications

The policy implications flowing from this study are of two types. A number of narrow-gauge propositions flow from the specific findings about laboratory behavior. But the study also raises questions about

broad, "macro-policy" issues pertaining to the allocation of resources among diverse institutional actors. We begin this section with a discussion of the narrow propositions regarding R&D laboratory behavior.

Policy Propositions

This study was designed to investigate structural and behavioral differences among R&D laboratories, but structural issues addresses are fundamental to many crucial policy questions. The case evidence presented here is not definitive and, thus, policy propositions flowing from this analysis are merely suggestive. The propositions presented below are consistent with the findings of the present study, but the propositions are, essentially, a policy research agenda.

1. Organizational stability is associated with low levels of conflict between government and market influences. If stability is prized, policy-makers are perhaps well-advised to ensure that government and market forces are not at loggerheads. Stability is not, of course, a cardinal value. Organizational change, even radical change, is sometimes beneficial. However, it is commonly observed (Miller, 1977; Gregory, 1969; Parmenter and Garber, 1971) that R&D policy that proceeds in fits and jerks with no consistent direction is a major factor in R&D failure. At least in those cases where R&D success requires long term commitment to objectives, R&D is best provided by an organization not buffeted by conflicting market and government goals. This seems to imply that heavy government financing of research directed toward proprietary products is often ill-advised. Likewise, this proposition seems to provide an explanation of at least one of the factors related to the

conflicts often observed in basic research units housed in industrial organizations and cooperatives (Twiss, 1980; Cooper, 1978).

2. The production of generic R&D products which might be used as an infratechnology base is best carried out in R&D establishments characterized by high degrees of publicness. Generic R&D labs with low publicness tend to lack the stability required for development of generic technology.

3. Strong market influence, regardless of level of publicness, reduces planning horizons and results in frequent program changes. As a result, long term research efforts are best carried out in environments with moderate to weak market influence.

4. Government incentives directed at industry affect not only the composition of R&D in particular firms, but may also result in fundamental structural change. Increased publicness (including not only direct financing but other policy interventions as well), changes the character of organizations and may be a major determinant of evolutionary processes for R&D laboratories. The implication is that tax incentives, government R&D contracts, and other such support mechanisms should be monitored not only to determine influence on directions of R&D but also with respect to possible structural impacts that may be more far-reaching and permanent. It is possible, for example, that government R&D incentives may result in the evolution of a laboratory from independent market to quasi-public market with all the attendant changes in environment and behavior.

5. Technology transfer policies should be differentiated from knowledge transfer policies and should be tailored to laboratory type.

Currently there is a growing concern in the United States that the so-called national laboratories (most of which would be classed as Public Generic laboratories) redeem the sizeable investment in public funds by technology transfer to industry (Morone and Ivins, 1982). In light of the success that the national laboratories have had in providing infratechnology and generic R&D products, a redirection toward the marketplace may be ill-advised considering the findings of conflicting market and generic goals. Knowledge transfer provides quite different benefits and entails substantially different processes than technology transfer (Technology and Information Policy Workshop, 1985). Our findings suggest transfer policies designed for implementation in public generic laboratories should focus on knowledge transfer rather than technology transfer.

Macro Policy Issues

While the findings about the publicness of R&D laboratories seem to suggest a number of managerial propositions, the entire thrust of the study calls into question one of the more significant policy assumptions of our time: that certain tasks are performed best by government, others are performed best by industry, and much of the art of policy-making is delineation of the appropriate boundaries so that tasks can be wisely allocated between government and industry.

The findings presented here can be interpreted in two very different lights. According to one perspective, the division of labor between government and industrial is badly out of kilter. Government entities are producing generic technologies, consistent with public good rationales for division of responsibilities, but they are also producing tech-

nologies clearly aimed, even during the short term, at the marketplace. Likewise, industry is not only driven by market demands and forces of competition but is also producing technologies that would seem to offer little prospect for short or even intermediate-term commercial benefit. One reaction to this state of affairs is that action must be taken to correct the mismatch of tasks and responsibilities with traditional sector-based stereotypes for allocation. A policy response based on a sector alignment assumption, that is, that organizational duties should align with the supposed performance advantages of the respective sectors, would seek to somehow get the laboratories, now obviously out of alignment back in correspondence with traditional roles.

The sector alignment assumption can be contrasted with what is termed a requisite variety assumption (Thompson, 1967). By this view, the lack of correspondence between stereotyped allocation of responsibilities and actual allocation is no cause for remedial action and may actually be beneficial. If one assumes that policy performance is accommodated by matching performance requirements to appropriate institutional structure (and that sector affiliation is not the sole factor in assessments) then the variety provided by the diverse mix of products and organizational characteristics of providers is salutary.

The findings presented here indicate that, regardless of one's policy sympathies, that the sector alignment assumption is not a plausible basis for R&D policy. Only about half of the laboratories examined here are amenable to conventional classification as governmental or industrial. Theoretically, it is possible to initiate radical changes in the institutional structure of R&D laboratories so as to reduce the

number of "mixed types" but from a practical standpoint such a policy makes little political or economic sense. If the government lab-industry lab stereotype is no longer valid, there seems little hope for policy assumptions based on classical ownership stereotypes. Whether or not a sector-alignment strategy makes sense for R&D policy, it is not, at least in its simple form, feasible.

One is not led inexorably to conclude that traditional policies based on sector distinctions are to be altogether abandoned. A revised alignment policy might be envisioned, a policy seeking to accommodate the reality of mixed type R&D labs. Such a policy strategy might, for example, seek to ensure that government laboratories focus on generic R&D products, that government laboratories eschew R&D aimed at the generation of proprietary products and short-term results, and that mixed type laboratories have a broad R&D product base and, perhaps, seek to exploit any synergisms that occur from simultaneous pursuit of applied and basic research needs. While such a revised alignment policy is not our preferred R&D policy strategy, the findings presented here and R&D effectiveness findings presented elsewhere (Crow, 1985) suggest that such a strategy has some merit. While industrial laboratories producing generic products have met with some success, government laboratories focusing primarily on proprietary R&D products have in general proved ineffective.

In our view, a policy strategy based on requisite variety assumptions is not only more realistic but also more likely to prove productive. The evolution of R&D organizations has been determined by a variety of complex and interacting factors including systematic public

policy, systematic business policy, market constraint, political competition, and virtually random organizational drift. It is not accurate to say that the various patterns of structural and institutional evolution have been invariably adaptive or even innovative. Nevertheless, this evolutionary process has produced great variety among R&D organizations and there is reason to believe that many of the new organizational forms and "hybrids" represent successful responses to changed economic, political and technological environments. If a stringent sector alignment policy strategy had been pursued, had "privatization" (Savas, 1981) criteria ruled R&D policy, it is likely that organizational structures would have been more static and that many beneficial and adaptive changes in R&D providers would not haveoccurred.

A requisite variety policy strategy does not, however, require unfettered evolution. A key component of a successful policy based on institutional and structural variety is continual monitoring, assessing and adjusting. The more or less natural evolution of R&D laboratories should be complemented by systematic attempts to assess the effectiveness of particular structural arrangements in connection with particular R&D objectives and there appears to be no good reason why such assessments should be guided by conventional stereotypes about the comparative advantages of government and industrial laboratories. If, for example, it is determined that government laboratories of a particular structural type are quite effective in producing certain market-oriented, proprietary R&D products, there is no reason to worry greatly about the failure of conventional wisdom.

Footnotes

[1]Research for this paper was supported by the Andrew W. Mellon Foundation, the Institute for Mining and Minerals Research at the University of Kentucky and by the Technology and Information Policy Program at the Maxwell School, Syracuse University.

[2]Examples of organizational and policy research which uses this stereotype as a key assumption are well reviewed in Blume (1974). Further examples of the broad use of this stereotype include; Box and Cotgrove, 1968; Muller, 1967; Avery, 1960; Brown and Shepard, 1965. Freeman (1982) illustrates the use of these stereotypes in economic related technical change theory.

[3]For elaboration of the dimensional publicness concept see Bozeman, 1984; Bozeman and Straussman, 1983; Crow, 1985; Emmert and Crow, 1985. Our paper takes the "dimensional" (as opposed to the traditional dichotomous) approach to publicness and applies the approach to the analysis of R&D labs.

[4]The R&D product variable was subjectively measured through questionnaire response on product end use and product type. To validate our assessment, participants in the study were queried as to their assessment of the validity of the categorization for their particular laboratory.

[5]To begin the process of testing the utility of this new classification scheme, a study population was drawn from the universe of more than 12,500 research and development laboratories in the United States and Canada (Catell Press, 1970; 1983; Gill, 1985; Watkins and Ruffner, 1984). The study population (N=829) represents the total group of R&D

laboratories pursuing energy or energy related research in the US and Canada.

[6]By directorate, it is implied that interviews were carried out with either the laboratory director(s) and/or member(s) of the technical management staff at the laboratory.

[7]Local/neutral type changes are those defined by Paul David as attempts to reduce the latency of existive technological alternatives. In this model, technical change is seen as a neutral process which is both evolutionary and historical. Local in this definition encompasses incremental and adaptive change only. An excellent summary of David's and other competing theories of technical change is presented by Elster (1983).

TABLE I

CLASSIFICATION SCHEME FOR R&D LABORATORIES

LEVEL OF MARKET INFLUENCE (Nature of R&D Product)	LEVEL OF GOVERNMENT INFLUENCE (Publicness)		
	HIGH	MODERATE	LOW
Generic	Cell I Environment: Public Generic	Cell II Environment: Quasi-Public Generic	Cell III Environment: Independent Generic
Balanced	Cell IV Environment: Public Multi-Market	Cell V Environment: Quasi-Public Multi-Market	Cell VI Environment: Independent Multi-Market
Proprietary	Cell VII Environment: Public Market	Cell VIII Environment: Quasi-Public Market	Cell IX Environment: Independent Market

TABLE II

CLASSIFICATION BY OWNERSHIP OF THE STUDY POPULATION

Ownership Class	Number of Units	Category Description
Industrial	258 (31.1%)	Laboratory facilities are owned by an industrial organization.
Government	74 (8.9%)	Laboratory facilities and programs are owned and operated by an agency of the government.
Cooperative	414 (49.9%)	Laboratory facilities and programs are cooperatively owned and operated by more than one organizational type.
Mixed	83 (10%)	The laboratory has portions of its' facilities and programs owned by an industrial concern or university and portions owned by a government agency.
Total	829 (100%)	

TABLE III

OWNERSHIP DISTRIBUTION OF RESPONDENTS

Ownership	Frequency	Percent	Cum Percent
Industrial	46	18.4	18.4
Govt. Agency	41	16.4	34.8
Cooperative	140	56.0	90.8
Mixed	23	9.2	100.0
Total	250	100.0	

Table IV

CLASSIFICATION OF R&D ORGANIZATIONS BY ENVIRONMENTAL INFLUENCE

LEVEL OF MARKET INFLUENCE (Nature of R & D Products)	LEVEL OF GOVERNMENTAL INFLUENCE: High	Moderate	Low	Row Total
Generic Product (Low)	Public Generic	Quasi-Public Generic	Independent Generic	
Total	121	40	6	167
Row %	72.5	24	3.6	68.2
Column %	89.6	64.5	12.5	
Total %	49.4	16.3	2.4	
Balanced Product (Moderate)	Public Multi-Market	Quasi-Public Multi-Market	Independent Multi-Market	
	4	11	10	25
	16	44	40	10.2
	3	17.7	20.8	
	1.6	4.5	4.1	
Proprietary Product (High)	Public Market	Quasi-Public Market	Independent Market	
	10	11	32	245
	18.9	20.8	60.4	100.0
	7.4	17.7	66.7	
	4.1	4.5	13.1

TABLE VI

LABORATORY CHARACTERISTICS BY VARIOUS LEVELS OF ENVIRONMENTAL INFLUENCE

LEVEL OF MARKET INFLUENCE (Nature of R&D Product)	LEVEL OF GOVERNMENT INFLUENCE (Publicness)		
	High	Moderate	Low
	Public Generic	Quasi-Public Generic	Independent Generic
Generic	N = 121 A = 1958 F = $2.95 GI = 2.13 Obj = 5.68	N = 40 A = 1957 F = $1.2 GI = 2.52 Obj = 5.30	N = 6 A = 1953 F = $.753 GI = 3.83 Obj = 4.4
	Public Multi-Market	Quasi-Public Multi-Market	Independent Multi-Market
Balanced	N = 4 A = 1961 F = .692 GI = 2.29 Obj = 5.75	N = 11 A = 1958 F = $2.0 GI = 3.27 Obj = 3.36	N = 10 A = 1940 F = $8.4 GI = 4.8 Obj = 2.1
	Public Market	Quasi-Public Market	Independent Market
Proprietary	N = 10 A = 1959 F = $5.66 GI = 2.5 Obj = 4.3	N = 11 A = 1957 F = $1.5 GI = 3.18 Obj = 2.18	N = 30 A = 1953 F = $6.795 GI = 4.75 Obj = 1.63

KEY:

N = Number of Observations
A = Average Year of Laboratory Startup
F = Median Annual Funding (millions of dollars)
GI = Average Level of Government Influence where 1 = dependent and 5 = independent
Obj = Research objectives of laboratory where 1 = short-range applied and 8 = long-range basic research.

TABLE VII
PUBLIC SECTOR LABORATORIES
CASE STUDY CHARACTERISTICS

	Ownership	Laboratory Funding	Total Lab Staff	Approximate Annual Budget ($ in millions)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Some Aviation Corporate Research Center (Case 12)	Industrial	1956	15	$+.3	Broad, nationally oriented research which is directed toward the search for new technological alternatives within the parent firm the operating divisions conduct product-process oriented research. In contrast, the results of this lab research are generally published in the open literature and available technical reports.	Research undertaken is directed toward new technological alternatives more than to existing technologies. The goal of the laboratory is to supply or develop the array of scientific options available for various technological applications. Examples include basic research in materials, lasers, analytical techniques and bioelectronics.	Research is undertaken almost solely on the scientific frontier. The time horizon for potential research applications is 15-20 years.	Research planning in this industrially owned lab is carried out in a multistage process with the government. R&D planning is carried out on a multi-year time frame with single year plans being persistently disrupted.	Funding for the laboratory is derived largely as a function of the parent firms sales to the government. In addition, because of the institutional need R&D planning carried out with the government lab has been var, stable.	The laboratory is a separate research facility of a parent corporation with several [illegible] which research is carried out in [illegible] based research groups which are centered around a principal research [illegible]. The laboratory structure, with its five [illegible], centered groups, is of [illegible] flow [illegible].
Energy Pollution Research Laboratory (Case 10)	Government	1970	80	$0.5	Broad, nationally oriented research directed toward the search for new technologies for [illegible] energy based pollutants	The research is directed toward the search for new technologies for [illegible] energy based pollutants.	Because the research is directed toward new alternatives for pollution control on new energy technologies rather than on the technologies themselves, it is carried out on the scientific and technological frontiers. The time horizon for research is 15-20 years.	Organizational stability from a financial perspective was too high. From a structural perspective the lab did experience instability resulting from frequent reorganization.	Planning is multi-year by lab gr with very heavy emphasis on current year planning.	Structurally, the lab is a [illegible] operated by the parent agency as a part of this network the lab is nearly [illegible] to agency R&D management [illegible]. Internally the lab is [illegible] structured around agency research topics. From a [illegible] perspective, however, the research is managed by [illegible] specific projects.
Institute for Advanced Energy Research (Case 11)	Mixed Facilities owned by a university and a government agency)	1960	5+	$15.0	The scope of research at the lab is very broad within the area of energy and materials science. There is a national orientation toward the research.	Laboratory researchers are committed to the search for new science-based technological applications. There are no specific technologies envisaged only a narrow focus for future technological application.	Research is nearly totally focused on the scientific frontier. The time, however, for potential research applications, generally 15-20 years.	Five year research planning and one year planning, programming and budgeting are institutionalized.	The lab has experienced a very stable environment for nearly +0 years. Since [illegible], there has been only minor [illegible] budget changes.	Research is carried out by [illegible] research groups. These research groups are relatively [illegible] and are based on [illegible] lead structure.
Laser Science Center (Case 9A)	Cooperative Facilities and programs are cooperatively owned and operated by a university and a government agency.	1964	60	$ 2.0	The research scope for the lab is national within a narrow research topic. To a large extent this research lab is a unique national facility and is often sited and used from an international science perspective, in this regard.	Researchers are involved only in the search for new scientific knowledge. There is no direct relationship between research and its potential technological applications.	Research is totally focused on the scientific frontier with a very long range time horizon.	Five year research planning and one year planning, programming and budgeting are institutionalized.	The lab has experienced a very stable environment for nearly +0 years.	Research is carried out by [illegible] research groups. These research groups are relatively [illegible] and are based on [illegible] lead structure.
The Neutron Institute (Case 17B)	Cooperative (Facilities and programs are cooperatively owned and operated by a university and a government agency)	1950	140	$ 7.5	This research facility is dedicated to the national research community to [illegible] energy physics and as a result has a national orientation.	Researchers are involved only in the search for new scientific knowledge. There is no direct relationship between research and the potential technological applications.	Research is totally focused on the scientific frontier with a very long range time horizon.	Five year research planning and one year planning, programming and budgeting are institutionalized.	The lab has experienced a very stable environment for nearly 10 years.	Research is carried out by [illegible] research groups. These research groups are relatively [illegible] and are based on [illegible] lead structure.

TABLE VIII
QUASI-PUBLIC GENERIC LABORATORIES
CASE STUDY CHARACTERISTICS

	Financial Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Magnetic Science Center (Case 506)	Cooperative (Jointly owned and operated by a university and an agency)	1969	52	$1.35	Research is directed toward a few technological applications of magnetics and is not a coordinated comprehensive program.	Research is basically evolutionary, attempting to take existing technological alternatives to magnetics and improve them. There is little searching for new alternatives.	The focus on existing techniques and their new modifications limits the research to the achievement/technological frontier. The time horizon for research is 5-10 years.	The lab receives no regular or institutional funding on a continuing basis. As a result, research planning is limited to a one year time horizon.	Because of the lack of an stable funding source, the lab has experienced a very unstable funding environment. Research funding is pieced together on a contract by contract basis.	Organized around principal investigator led research groups. The laboratory organization is a loose federation. Research groups come and go dependent on funding.
California Cyclotron Center (Case 760)	Cooperative (Jointly owned and operated by a university and an agency)	1970	35	$1.2	Lab activities are primarily directed toward the conduct of projects around the capability of a specialized research facility. The projects are not coordinated and are not directed toward any particular research agenda.	With the goal of furthering the development of existing technologies there is little searching for new technological alternatives.	The lab's goal is to assist in the development and application of technology through the utilization of the specialized research facility. In this regard, the research is directed toward improving existing technologies on the achievement and technological frontier. The time horizon for research is 5-15 years.	Research planning is carried out as a means of optimizing lab performance. This research planning was on an annual to bi-annual basis.	Since its inception, the lab has experienced instability. Funding is highly variable and the face of research changes often.	The lab staff is organized around several topical research groups. These groups are PI led and frequently change.
Energy Research Inc (Case 293)	Mixed (The facilities are partially owned by a private research company and various agencies of the government)	1966	110	$8.0	Research activities are directed toward particular energy systems and their associated efficiencies. The research is mainly focused and the projects are not coordinated.	Existing technologies are the focus of the lab. Of particular importance is improving the performance of a wide array of existing technological options. There is little searching for new alternatives.	The research of the lab is directed toward the improvement of existing technological options (achievement frontier) and on occasion alternatives available on the technological frontier. The time horizon is 3-10 years.	Research planning is quite difficult because nearly all research is carried out in response to requests for proposals.	As a result of following RFP's as the principal means of organizational funding, the lab has experienced substantial budget and program/matrix fluctuations.	The lab staff is organized around several topical research groups. These groups are PI led and frequently change
Institute for Solar System Development (Case 517)	Cooperative (Jointly owned and operated by a university and an agency)	1972	30	$1.5	The lab is directed toward research and production of specialized solar materials. The materials research is not comprehensive in nature and is focused on particular materials for limited settings.	Given that the scope of research is on a limited set of existing materials it is fair to conclude that the lab is not involved in search based technical change.	Because of the limited direct application of the materials the research focus of the lab is on the technological frontier. The time horizon is 5-10 years.	Most research is sponsored through RFP funding mechanisms, as a result research planning is difficult. There is an attempt, however, to plan a general cause for the lab on an annual or biannual basis.	Funding shifts have been dramatic and the lab has yet to find a stable funding base. It desires to have increased stability but has been elusive.	The lab staff is organized around several topical research groups. These groups are PI led and frequently change

TABLE 11
INDEPENDENT GENERIC LABORATORIES
CASE STUDY CHARACTERISTICS

	Classical Ownership	Laboratory Founding	Total Lab Staff	Approximate Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Chemical Processing Institute (Case 903)	Cooperative (Jointly owned and operated by a university and several industrial partners)	1983	10	$ .2	The lab is directed toward assisting a group of industrial firms in solving their particular chemical processing problems. The agenda does include new technology development but only within the scope of the existing needs of the research cooperative.	The technical change focus of the lab is on existing technologies. There is no significant effort which is directed toward the search for new technological options in chemical processing.	Improving the technologies on the achievement frontier and applying these on the technological frontier is the focus of this lab. The time horizon for research is 10-20 years.	Research planning is in its early stages because of the youth of the lab. At present a 2 year planning horizon is being operationalized.	The lab has come about with some difficulty and its funding stability is questionable. The lab is dependent on a few industrial cooperators and as such has a small base.	Principal investigator led research groups are the latest general approach to structure
The Ionian Institute (Case 907)	Cooperative (Jointly owned and operated by several family foundations)	1979	50	Dr.5	The lab is focused toward the application of new technological alternatives in biological energy systems. The agenda, however, is not comprehensive.	Research focuses on biological energy applications to existing energy technology arrays. As a result, there is little search induced research.	The time horizon for research is 10-20 years with efforts principally directed toward the technological frontier. Some efforts are on the scientific frontier.	Because of funding uncertainties and the loosely federated structure, research planning beyond the project level occurs only on an annual to bi-annual basis.	With less than 15% of its funding being provided by the parents the lab has experienced a high level of funding uncertainty. This uncertainty has contributed to an unstable organizational environment.	A loose federation of principal investigator led research groups
Center for Advanced Energy Physics (Case 910)	Cooperative (Jointly owned and operated by a university and several agencies)	1957	95	$8.5	Lab activities are directed toward physics applications in energy and other technologies. These efforts are directed toward the particular problems of the cooperating agencies.	There is little search induced research undertaken. Problems investigated are given to the lab within the realm of existing technologies.	Research is carried out primarily on the technological frontier and on occasion the scientific frontier. The time horizon is 10-25 years.	Annual to bi-annual planning is carried out, but its effectiveness is limited by the loose nature of the structure.	Project funding is uncertain and base funding is unstable. The result has been a high level of instability.	A loose federation of principal investigator led research groups

TABLE 3
PUBLIC MULTI-MARKET LABORATORIES
CASE STUDY CHARACTERISTICS

	Classical Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
The State Energy Lab (Case 6Pt)	Governmental	1890	37	$ .75	Delivery of technical support and technical information on the state energy and national resources to industrial and public interest groups.	Neutral role is played by the lab in the development of info-technology data.	Research information produced is used to assist in the application of new technological alternatives.	Funding and planning are on a biennial basis. The planning system follows the same timetable as that of the parent government agency.	Direct political intervention into the goals, objectives and particular projects of the lab have led to both financial uncertainty and program instability.	The lab is organized around typically based departments. The structure is hierarchical with all research management following the established chain of command.
The State Energy Laboratory (Case 6It)	Governmental	1944	2,300	$133.5	The development of new technologies for particular industrial settings in the area of state energy and associated technologies.	The focus of research is on the existing technology base. The search for new technological alternatives has not been undertaken recently.	With a 5-10 year time horizon, research carried out is focused on the technological frontier.	Funding and planning are on a biennial basis. The planning system follows the same timetable as that of the parent government agency.	Direct political intervention into the goals, objectives and particular projects of the lab have led to both financial uncertainty and program instability.	The lab is organized around technology based departments. The structure is hierarchical.

TABLE XI
QUASI-PUBLIC/MULTI-MARKET LABORATORIES
CASE STUDY CHARACTERISTICS

	Classical Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in millions)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
The Magnetic Transport Center	Cooperative (Owned and operated by a University, several industries and several agencies)	1976	17	$ 0.2	The development of new advanced concepts in rapid ground transportation from a systemwide national perspective.	The focus of the lab is on the process of searching for and investigating new alternatives to the current array of technologies.	Research is focused on the technological frontier for those technologies discovered and on the scientific frontier for new alternatives. The time horizon for research is 5-20 years.	Planning is a formalized activity with substantial input from the cooperating partners. Planning is general on a 1-2 year time schedule.	Although having experienced some instability at various points in its history, the lab has entered a period of stability. This has resulted from the development of an agreed upon research agenda by the cooperating partners.	Principal investigator led research groups organized within a hierarchical structure.
General Energy Inc. (Case 0fld)	Industrial	1956	1,781	$150.0	The development of new advanced energy technologies across the spectrum of options.	The focus of the lab is on the process of searching for and investigating new alternatives to the current array of technologies.	Research is focused on developing new applications for options on the technological frontier and new permutations of various combinations of the various options. The time horizon is 5-30 years.	Research planning is a formalized corporate process within the lab itself and is on a two year time frame.	Stability in the lab has been exceptionally excellent in spite of several industrial ownership changes.	Topically structured departments with PI led research groups in areas of new emphasis.
Institute of Superconductivity (Case 611)	Cooperative (Owned and operated by a university and several industrial and government units)	1976	40	$ 1.0	To carry out a somewhat uniquely scoped effort designed to advance superconductivity based technologies.	To search for new applications and new knowledge regarding superconductivity.	Focused on both the technological and the scientific frontier the research of the lab has a 5-30 year time horizon.	Internal planning results in a research agenda which is marketed to the several interested cooperators.	Although funded by several sources, the lab is stable. This is the result of the development of a research plan rather than the pursuit of DFP's.	Principal investigator led research groups

TABLE XII
INDEPENDENT MULTI-MARKET LABORATORIES
CASE STUDY CHARACTERISTICS

	Classical Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Ewing Oil R&D Inc (Case 12a)	Industrial	1954	100	$ 6.1	An intrafirm research lab designed to assist in the general production of knowledge and the development of proprietary products and processes.	The focus of the lab is toward improving existing technological options rather than searching for new options.	Although the lab does have the desire to contribute to the generic technology base it can be fairly stated that all or most of its work occurs on the achievement frontier. Time horizon is 6 months or less to 2 years.	Planning is on an annual basis and is subject to frequent changes.	Market fluctuations have a strong negative effect on organizational stability.	Departmentally structured around the processes and products of the firm
Photo Chemicals Inc. (Case 3a)	Industrial	1971	101	$ 9.2	An intrafirm research lab designed to assist in the general production of knowledge and the development of proprietary products and processes.	The focus of the lab is toward improving existing technological options rather than searching for new options.	Although the lab does have the desire to contribute to the generic technology base it can be fairly stated that all or most of its work occurs on the achievement frontier. Time horizon is 6 months or less to 2 years.	Planning is on an annual basis and is subject to frequent changes.	Market fluctuations have a strong negative effect on organizational stability.	Departmentally structured around the processes and products of the firm
Seattle Toon Inc. (Case 31a)	Industrial	1940	12	$ 1.0	An intrafirm research lab designed to assist in the general production of knowledge and the development of proprietary products and processes.	The research focus of the lab is on improving the existing array of technological options available to the firm.	Although the lab does have the desire to contribute to the generic technology base it can be fairly stated that all or most of its work occurs on the achievement frontier. Time horizon is 6 months or less to 2 years.	Planning is on an annual basis and is subject to frequent changes.	Market fluctuations have a strong negative effect on organizational stability.	Departmentally structured around the processes and products of the firm
Minerals Research Laboratories Inc. (case 16b)	Mixed (Privately owned with joint operating contracts)	1961	125	$ 7.5	A research lab directed toward the immediate research problems of several firms in the energy/minerals business.	The research focus of the lab is on improving the existing array of technological options available to the firms.	Although the lab does have the desire to contribute to the generic technology base it can be fairly stated that all or most of its work occurs on the achievement frontier. Time horizon is 6 months or less to 2 years.	Planning occurs on a project basis with the individual contracting firms.	Research is totally a function of market. When the market is bad for the contracting firms, research is not carried out or cancelled.	Departmentally structured with semi-independent investigators serving as principals

TABLE 5111
PUBLIC MINERS LABORATORIES
CASE STUDY CHARACTERISTICS

	Classical Ownership	Laboratory Founding	Total Lab Staff	Normal Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Southwest Mining Laboratory (Case 5141)	Government	1962	117	$ 5.3	To deliver technical knowledge and research services to individual firms in a regionally based mining industry.	Existing technologies and their evolutionary development is the focus.	Research is limited to the achievement frontier with little or no studies on the technological frontier. Time horizon is immediate to 2 years.	Research planning follows government budget cycles only and is carried out as a means of addressing policy changes in the parent agency. Although research is planned on a two year time frame such plans are subject to frequent change.	High levels of politicization in the labs operation have led to uncertainty and instability.	Divisional research structure in technology areas.
The Provincial Mining Laboratory (Case 853)	Government	1968	135	$ 5.1	To deliver technical knowledge and research services to individual firms in a regionally based mining industry.	Existing technologies and their evolutionary development is the focus.	Research is limited to the achievement frontier with little or no studies on the technological frontier. Time horizon is immediate to 2 years.	Research planning follows government budget cycles only and is carried out as a means of addressing policy changes in the parent agency. Although research is planned on a two year time frame such plans are subject to frequent change.	High levels of politicization in the labs operation have led to uncertainty and instability.	Divisional research structure in technology areas.
Advanced Propulsion Laboratory (Case 339)	Government	1972	150	$ 6.0	To deliver technical knowledge and research services in energy materials and environmental sciences for the <u>sole</u> consumption of the parent agency.	Existing technologies and their evolutionary development is the focus.	Research is limited to the achievement frontier with little or no studies on the technological frontier. Time horizon is immediate to 2 years.	Research planning follows government budget cycles only and is carried out as a means of addressing policy changes in the parent agency. Although research is planned on a two year time frame such plans are subject to frequent change.	High levels of politicization in the labs operation have led to uncertainty and instability.	Divisional research structure in technology areas.
Underwater Energy Systems Center (Case 495)	Cooperative (Jointly owned and operated by a university and an agency)	1965	205	$16.0	The development of underwater energy systems for the <u>sole</u> consumption of the cooperating agency.	This lab has overall responsibility for the evolutionary development of this particular technology. As a part of this process, there is little research induced technical advance.	Research is limited to the achievement frontier with little or no studies on the technological frontier. Time horizon is immediate to 2 years.	Research planning follows government budget cycles only and is carried out as a means of addressing policy changes in the parent agency. Although research is planned on a two year time frame such plans are subject to frequent change.	This lab is more stable than the others of this type because it is slightly more independent.	...o.e.dna. research structure in technology areas. There are some P... based research groups, particularly when faculty from the cooperating university are involved.

TABLE XIV
QUASI-PUBLIC MARKET LABORATORIES
CASE STUDY CHARACTERISTICS

	Closeness Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Energy Engineering Inc. (Case 120)	Industrial	1976	25	$ 1.25	The development of proprietary energy engineering related technologies for marketing in the competitive arena.	The focus of the lab is on further development of existing technologies and not the search for new alternatives.	Research is largely limited to the achievement frontier. Although knowledge from and experience on the technological frontier is desired.	Research planning is done on an annual basis and follows general product marketing cycles. In addition plans are developed for the integration of marketing and development plans with government research support.	Funding for research comes from the government, various industries and in theory from users sales. As a result of the large number of sources there is high uncertainty. This uncertainty has resulted in a moderate level of instability.	Divisionally organized around products.
Regional Energy Research Center (Case 88)	Mixed (Owned in part by a university and in part by a government with industrial funding)	1967	15	$ .8	The development of energy related data and knowledge for individual firms in the region.	The focus of the lab is on further development of existing technologies and not the search for new alternatives.	Research is limited to the achievement frontier. Problems investigated are current technical needs in the regional energy industry.	Research planning is on a project by project basis with a very limited overall plan guiding the labs activities.	Due to the lack of an ongoing stable funding source and due to the inability to regain critical mass the lab is very unstable.	Project organized around a loose divisional structure.
Advanced Turbine Research (Case 315)	Industrial	1958	26	$ 2.0	The development of proprietary energy engineering related technologies for marketing in the competitive arena.	The focus of the lab is on further development of existing technologies and not the search for new alternatives.	Research is largely limited to the achievement frontier. Although knowledge from and experience on the technological frontier is desired.	Research planning is done on an annual basis and follows general product marketing cycles. In addition plans are developed for the integration of marketing and development plans with government research support.	Funding for research comes from the government at certain stages and the parent at other stages of the research. As a result, it is very uncertain.	Divisionally organized around products.

TABLE IV
INDEPENDENT MARKET LABORATORIES
CASE STUDY CHARACTERISTICS

	Ownership	Laboratory Founding	Total Lab Staff	Approx Annual Budget ($ in million)	Research Scope	Type of Technical Change	Research Frontier	Research Planning	Organizational Stability	Organizational Structure
Power Systems Laboratory Inc. (Case 03)	Industrial	1947	60	$00.0	The development of products and processes for marketing by the parent firm.	Basically an evolutionary research process of further development of existing technologies and the occasional search for new alternatives.	Research occurs both on the achievement frontier and the technological frontier. With the focus shifting as driven by market conditions.	Research planning is very formalized in an annual program planning and proposal development process.	The structure, funding patterns and insulation from market downturns has resulted in lab stability.	Standard product/process oriented research divisions.
Smith Chemical Research Laboratory (Case 319)	Industrial	1961	120	$ 6.6	The development of products and processes for marketing by the parent firm.	Basically an evolutionary research process of further development of existing technologies and the occasional search for new alternatives.	Research occurs both on the achievement frontier and the technological frontier. With the focus shifting as driven by market conditions.	Research planning is very formalized in an annual program planning and proposal development process.	The structure, funding patterns and insulation from market downturns has resulted in lab stability.	Standard product/process oriented research divisions.
Black Forest Energy Lab Inc (Case 150)	Industrial	1976	20	$ 1.75	The development of products and processes for marketing by the parent firm.	An evolutionary research process designed to improve current products and processes incrementally.	Research is predominantly carried out on the achievement frontier.	Research planning is very formalized in an annual program planning and proposal development process.	Relatively less stable than the other Independent Market Labs but organizationally redesigning to provide for insulation from the market.	Standard product/process oriented research divisions.
Metalville Research Center (Case 295)	Industrial	1947	400	$25.0	The development of products and processes for marketing by the parent firm.	Basically an evolutionary research process of further development of existing technologies and the occasional search for new alternatives.	Research occurs both on the achievement frontier and the technological frontier. With the focus shifting as driven by market conditions.	Research planning is very formalized in an annual program planning and proposal development process.	The structure, funding patterns and insulation from market downturns has resulted in lab stability.	Standard product/process oriented research divisions.

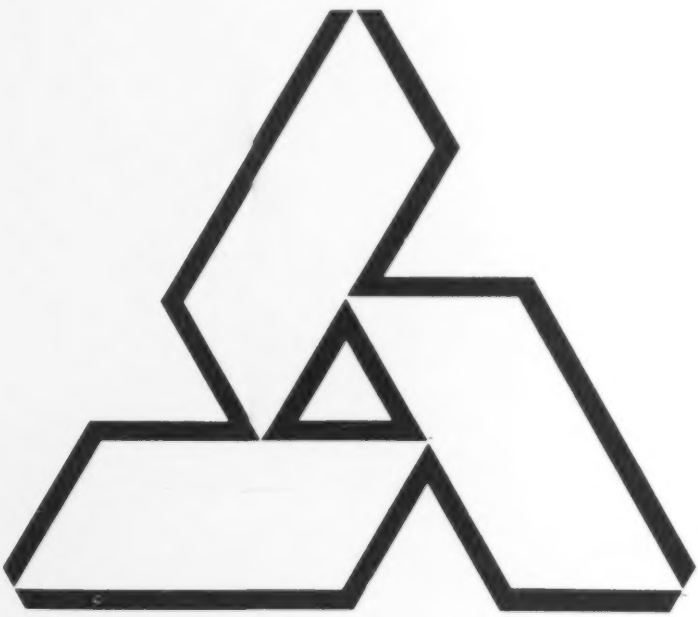
APPENDIX 3

Joint Council on
Food and
Agricultural Sciences

January 1984

Summary: Needs Assessment for the Food and Agricultural Sciences

A Report to the Congress from the Secretary of Agriculture



The Joint Council on Food and Agricultural Sciences was established in 1977 to encourage and coordinate research, extension, and higher education activities in the food and agricultural sciences. This role was strengthened in the Agriculture and Food Act of 1981, which directed the Department to improve the planning and coordination of research, extension, and higher education within the public and private sectors and to relate the federal budget process to the overall functioning of the system.

The Joint Council identified four reports which will work towards improving the overall effectiveness of the food and agricultural system.

A long-term **needs assessment** (20-30 years) for food, fiber, and forest products, including a discussion of the research, extension, and higher education requirements for meeting the identified needs. (This task was assigned to the Secretary of Agriculture in the Agriculture and Food Act of 1981. He requested the Joint Council to fulfill this responsibility). The needs assessment report was prepared and published in two separate documents. One is the *Reference Document: Needs Assessment for the Food and Agricultural Sciences* and the other is the *Summary: Needs Assessment for the Food and Agricultural Sciences*.

A **five-year plan** to reflect the coordinated goals and objectives of the research, extension, and higher education community. This report will be completed in February 1984, followed by biannual updates.

An **annual priorities report** on research, extension, and higher education, which presents the Joint Council's priorities for the next fiscal year, the required financial support, and suggested federal, state, and private-sector roles. This report will be completed by June 30 of each year.

An **annual accomplishment report** which specifies the ongoing research, extension and higher education programs and respective accomplishments, along with expectations for the future. This report will be completed by November 30 of each year.

These four reports are inter-related although each is published separately. They constitute an overall strategic planning process which will eventually provide the food and agricultural science system with a means of assessing short-term and long-term future needs and reflecting on past accomplishments. It also will provide a foundation for planning the most effective and efficient means for meeting the future demands for food, fiber, and forest products. These four reports offer a continuing mechanism by which the research, extension, and higher education programs can assess future needs.

The symbol appearing on the front cover represents the purpose of the Joint Council (i.e., to improve planning and coordination among research, extension, and higher education) and the cooperative character of the food and agricultural science system within federal, state, and private organizations.

DEPARTMENT OF AGRICULTURE
OFFICE OF THE SECRETARY
WASHINGTON, D.C. 20250

January 30, 1984

Honorable Thomas P. O'Neill, Jr.
Speaker of the House of Representatives
Washington, D.C. 20515

Dear Mr. Speaker:

Transmitted herewith, pursuant to Section 1405 of the Agriculture and Food Act of 1981, is a "Needs Assessment for Food and Agricultural Sciences." This assessment deals with long term needs for food, fiber, and forest products and the needed supporting role of research, extension, and higher education programs.

At my request, the Joint Council on Food and Agricultural Sciences directed the preparation of the two enclosed reports:

- **Needs Assessment Reference Document** -- a 300-page report that contains 15 separate papers authored by 40 nationally prominent scientists and administrators; and

- **Needs Assessment Summary Document** -- that highlights the findings in the reference document and other recent planning reports of science and education performers in agriculture.

These reports demonstrate that the decentralized science and education system in agriculture can: 1) plan for the future in a coordinated and forward looking manner; 2) address the changing needs of farmers and consumers; and 3) be a major force in improving productivity and overall industry well being. A similar letter was sent to the President of the Senate.

Sincerely,

John Block

John R. Block
Secretary

Enclosures

Summary: Needs Assessment for the Food and Agricultural Sciences

A Report to the Congress from the Secretary of Agriculture

Contents

EXECUTIVE SUMMARY v

I. Introduction 1
A. Recent Changes Requiring a New Technological Base for Agriculture 1
B. Basis for Needs Assessment Summary 4

II. Multiple Demands Facing U.S. Agriculture as the Nation Approaches the Year 2000 and Beyond 6
A. Projected Needs for Food, Fiber, and Forest Products 6
B. Sustaining and Improving Productivity 15
C. Adequacy of the Natural Resource Base and Environmental Concerns 18
D. Providing Nutritious, Safe, and High-Quality Products 21

III. How Science and Education Can Help U.S. Agriculture Meet Changing Demands 23
A. Natural Resources 23
B. Production Agriculture 31
C. Processing, Marketing, and Distribution 39
D. Agricultural Policy—Including Adjustment Concerns 42
E. Families and Communities 45
F. International Activities 50

Appendix B—Source Documents 71
Appendix C—Joint Council Membership List 74

The Joint Council wishes to express its appreciation to the Needs Assessment Staff Group who prepared this summary.

Team leader: Paul F. O'Connell—FS
Other team members include: W. Joseph Lanham—ES,
Charles B. Rumburg—CSRS, Jane E. Roth—OGPS,
Sheila H. Gillette—ARS, Geri C. Richmond—OGPS.
Typing was done by Adrienne P. Baylor.
Special appreciation goes to Robert E. Buckman for his overall guidance and encouragement.

Executive Summary

The success of American agriculture is widely recognized. It has a tremendous capacity to produce and its production is highly efficient. Collectively, the food, fiber, and forest industries represent a major national asset in terms of world trade, international security, and domestic stability. Our Nation can reasonably expect an assured and reliable supply of agricultural and forestry products now and in the foreseeable future. The policy of providing public support for agricultural research and education underlies the current ability of U.S. producers to compete in world markets and to provide American consumers with high-quality and reasonably priced food, clothing, and shelter. However, past achievements will not automatically assure continued growth in productivity and industry well-being. Vast changes are underway that require a new technological base for agriculture.

- Past productivity improvements resulted from relatively low-priced land, water, fuel, chemical, and capital inputs. Since costs of these inputs have risen substantially, and will undoubtedly continue to rise, *alternate production technologies must be developed* to keep food, fiber, and forest product prices in line with past and current relative levels.

- Science has demonstrated a capability to *understand and fundamentally alter the processes of living cells.* These new abilities, along with other advances in such areas as microculture, cell fusion, regeneration of plants from single cells, and embryo recovery and transfer, are creating vast new opportunities all across the agricultural sciences.

- Advancements in computer technology enhance the computer's usefulness in analysis and transfer of information. The American agricultural system has long known that ready access to the right information at the right time is the key to success in managing inputs, production, marketing and distribution, and consumption of food, fiber, and forest products.

- There are increasing concerns about the *continued availability of the soil and water resource base.* Improved resource-saving technologies must be incorporated into our current production technologies.

- Modern agriculture depends heavily on chemicals. *The challenge is to develop chemical systems which are more highly targeted to their beneficial consequences* and which cause fewer environmental hazards.

- There is increased public awareness of the relationship between *personal well-being and diet.* Changing life styles and the increasing average age of U.S. citizens have led to questions about our nutritional needs.

• United States agriculture is becoming more *interdependent with domestic and world credit, trade, and exchange rate policies.* What national policy options can best cope with market variations (plus weather uncertainties) and also address needs of family farms, natural resource issues, and concerns of the taxpaying public?

To maintain the preeminence of United States agriculture, we must address these opportunities and issues. A critical element in meeting these challenges is *the ability of the agricultural science and education system to attract and/or train scientists and specialists with the needed skills,* e.g., molecular genetics, human nutrition, soil and water sciences, international marketing, systems analysis, and agricultural engineering.

Areas of concern include:

• Salary levels and promotion opportunities in the USDA/state system make it very difficult to retain highly qualified people in the high-tech fields.
• Graduate and undergraduate education programs are not attracting sufficient numbers of students in the critical fields.
• The average age of scientists is increasing. The formal education of many scientists is now 20 to 30 years old.

The technology development process must continue to consider *the incentives of final users.* Before new or existing techniques are adopted by an owner, manager, or consumer, many questions need answers. Will an alternative approach be more cost-effective? Can the farmer afford the additional cost when the prices of wheat, corn, or stumpage are so variable? What financial plan best fits a given farm or household? The unique aspect of agriculture is the *extension education process.* State specialists and county agents who interact regularly with the researchers also have the trust and understanding of producers and consumers. They take available research data from multiple sources and develop educational packages that consider the needs of users.

Demand-Supply Projections

At real prices approximating those of 1979-81, *effective global demand* (consumption) for agricultural and forest products is projected to expand substantially by 2000, primarily as a result of population and economic growth—about 60 percent for income-sensitive commodities such as meat, oilseeds, and processed forest products; close to 50 percent for cereal grains; and 35 to 40 percent for milk and natural fibers. By 2020, effective demand could more than double for income-sensitive commodities and could increase as much as 90 percent for cereal grains.

Output of U.S. agricultural and forest products increased nearly 40 percent in the past two decades. By 2000, production of cereal grains, oilseeds, and forest products will need to increase another 30 to 40 percent and that of other major products perhaps 20 percent. By 2020, needed production of major crops may be 70 to 100 percent above that of recent years to meet projected growth in demand from domestic and foreign markets.

For the remainder of this century and into the 21st century, the growth in demand for U.S. grains, oilseeds, and cotton will derive primarily from expansion of foreign demand. Currently (1982 figures), the United States imports about the same volume of wood products as it exports—$8.4 billion of imports versus $7.2 billion of exports. Current projections suggest little change in this position, so most growth in demand will be from domestic markets. However, the United States has a great opportunity to expand its export of forest products because: 1) world demand for paper and solid products is expected to grow, 2) many established wood-producing nations are confronted with diminished supplies; and 3) the United States has an abundant wood resource and a well-developed wood industry infrastructure. Growth in demand for meat and milk will be largely in domestic markets.

By 2000, close to 60 percent of the total consumption of U.S. cotton and soybeans and 40 percent of the consumption of cereal grains will be in foreign markets. Although projected increases in export demand are substantial—64 percent for oilseeds, 53 percent for cereals, 43 percent for cotton lint—growth rates will be well below those of the 1970's when exports of cereal grains tripled and those of oilseeds and cotton doubled. The result of these developments will be twofold: U.S. agriculture will become increasingly cash crop dependent and increasingly export dependent.

Role of Science and Education

Expanding productive capacity to permit a near doubling of output by 2020 *without major increases in real prices of food, fiber, and forest products* will require major public and private investments in science and education. New and improved technologies and better management systems will be needed to maintain and enhance resource productivity. Without continued growth in total factor productivity, there would be increased pressures on the natural resource base, increasingly serious environmental problems, and ultimately, higher real costs for food, fiber, and forest products.

- Increased production can occur without depleting the soil and water resource base if appropriate conservation practices and economic incentives can be more closely intertwined. A few possibilities include improvements in conservation tillage systems and better understanding of water stresses for both irrigated and dryland agriculture.

- The United States is rich in forests and related renewable natural resources. Intensive forest plantation management and use of alternative utilization technologies can satisfy an expanding domestic market and lead to improved world trade in forest products.

- Range resources in the United States cover enormous acreages, and have the potential for contributing much more to the economic and social well-being of the Nation. Grazing practices, range conditions, and wildlife habitats can be upgraded through improved understanding of range ecosystems.

- For both crop and animal agriculture there is a critical need to improve production efficiency. For crops, this includes enhanced genetic potential and improved yields in unfavorable environments. In animals, it involves improvements in animal feeding practices, genetic quality of stock, and animal health. Traditional technologies and new biotechnology techniques will both be explored in the pursuit of this goal.

- Post-harvest activities represent major portions of the retail cost of food, clothing, and shelter. In cooperation with the private sector, opportunities to improve transportation, processing, and packaging efficiencies need investigation.

- Policy issues needing study and clarification include: 1) the position of U.S. agriculture in the world economy; 2) effects of recent developments on size, cost, and asset distribution of farms; and 3) the role of the federal government in the domestic agricultural economy.

Future public investments in agricultural research and education should be based on more than generating technology *per se* or a simple multiplication of product output. Emphasis will be needed on the development and transfer of socially appropriate technologies that take into account not only agricultural and forest product needs but also goals concerning environmental quality; youth, family, and community development; human health and nutrition; and other sometimes competing social goals. In addition to investments in the physical and biological sciences, investments will be needed to enhance the effectiveness of institutions. The use of human development techniques and social science research can improve understanding of both human and institutional behavior.

To continue addressing the needs of U.S. agriculture, the science and education system needs to continually update and revitalize itself. It must train future scientists and managers, maintain and improve the knowledge base, have the necessary equipment and facilities, and take advantage of the new computerized information and analytical systems. It is important to remember that tomorrow's gain in scientific agriculture has its foundations in the healthiness and vitality of today's science and education community.

I. Introduction

The United States is a recognized world leader in agricultural production. This system, including related input and marketing components, generates about 20 percent of the Nation's gross national product and employs 23 percent of the U.S. labor force. Because of its diversity and efficiency, American consumers spend only 16 percent of their disposable income for food. American agricultural products are highly competitive in world markets, and their sale represents 18 percent of our total exports, contributing substantially to our balance of payments. As an industry, American agriculture has had a high rate of growth in productivity--a rate more than three times as high as that of the non-farm business sector of the economy since World War II.

Forestry also represents a significant portion of the U.S. economy. The latest comprehensive analysis shows that about $1 of every $18 of gross national product originated in some phase of timber growing, processing, and marketing. This figure does not include the important economic benefits that accrue from other forest-related uses such as hunting, fishing, camping, and grazing.

Lester C. Thurow, commenting in Newsweek magazine (1983) on the productivity of American agriculture, stated that its success "depended on more than good soil, good climate, and hard-working farmers, important as they were." He indicated that significant contribution has been made by government cooperation and funds that have been provided to the industry, especially for research and education. The federal government put major amounts of money into research, which was further developed at state experiment stations and passed along through county extension agents. "In agriculture, what started as a desperate effort to prop up a very large, sick industry in the 1930's ended as an industry that is the world's most efficient," said Thurow.

A. Recent Changes Requiring a New Technological[1] Base for Agriculture

Past achievements will not automatically assure continued growth in productivity and industry well-being. Vast changes are underway that require a new technological base for agriculture.

- Previous research focused upon obtaining high yields with little regard for controlling input levels. This occurred because of the relatively low costs for land, water, fuel, chemicals, and capital inputs. Since costs of these inputs have risen substantially, and will undoubtedly continue to rise, *alternate production technologies must be developed* to keep food, fiber, and forest product prices in line with current relative levels. In their 1983 "Recommendations" report, the National Agricultural Research and Extension Users Advisory Board made the input efficiency question their top priority.

[1]Technology refers to physical, biological, economic, and social techniques used to improve human sustenance and comfort.

• Science has demonstrated a capability to understand and fundamentally alter the processes of living cells. These new abilities, along with other advances in such areas as microculture, cell fusion, regeneration of plants from single cells, and embryo recovery and transfer, are creating vast new opportunities all across the agricultural sciences. The *tools of biotechnology* are being applied to viruses and bacteria, to insects and weeds, to plants and animals, in all stages of their life cycles from replication through aging.

• *Advancements in computer technology* enhance the computer's usefulness in analysis and transfer of information. The American agricultural system has long known that ready access to the right information at the right time is the key to success in managing inputs, production, marketing, distribution, and consumption of food, fiber, and forest products. The adoption of improved agricultural techniques continues to be limited by constraints such as: access to capital, awareness of appropriate technology, and awareness of feasible alternatives. Emerging information technologies hold the key to getting the right information to the right people at the right time and thus helping producers overcome current constraints in their operations.

• There are increasing concerns about the *continued availability of the natural resource base*. Inadequate management is damaging our soil and water resources. Improved resource-saving technologies must be incorporated into our current production technologies. What resource use patterns are consistent with sustained agricultural and forestry uses over time?

• Modern agriculture depends heavily on chemicals. All aspects of agriculture and forestry utilize chemicals in production as well as in processing and distribution. *The challenge is to develop chemical systems which are more highly targeted to their beneficial consequences and which cause fewer environmental hazards.* Some elements or compounds do not stay neatly within the narrow pathways for which they were intended, but are released to ground water, to surface water, to the air, to the soil, and to the food chain, causing both immediate and latent consequences which can be damaging.

• There is increased public awareness of the *relationship between personal well-being and diet*. Changing life styles and increasing average age of U.S. citizens have led to questions about nutritional needs. More emphasis on cereals, chicken, fish, vegetables, and fruits and suggestions that red meat, fat, and sugar make up smaller relative shares of our diet have major implications for agriculture. What are the long-term health consequences of these proposals? What are the relationships between food and mental well-being? What are the dietary needs of a population that lives longer?

• United States agriculture is becoming more *interdependent with domestic and world credit, trade, and exchange rate policies.* In combination with weather, these developments cause increased variations in prices received by U.S. farmers. What national policy options can best cope with market and weather uncertainties and also address needs of family farms, natural resource issues, and concerns of the taxpaying public?

If the preeminence of United States agriculture is to be maintained, these opportunities and issues require attention. A high priority need is *improved scientific expertise.* Currently, there are severe shortages of trained scientists to teach and conduct research in such areas as biotechnology, human nutrition, soil and water sciences, information sciences, international marketing, and agricultural engineering.

• One reason for this situation is that salary levels and promotion opportunities in the USDA/state system make it very difficult to retain highly qualified people in these high-tech fields.

• Graduate and undergraduate education programs in these fields are not attracting sufficient numbers of students to meet the need. At universities, research is inextricably linked with graduate education programs. The primary source of support is research formula funds, grants, and contracts. Agriculture must compete effectively for the limited number of students who acquire sound scientific preparation in the secondary schools.

• A third reason is the increasing average age of scientists. No matter how dedicated and hard-working such men and women may be, their output is often limited by their formal education experience, which may be 20 to 30 years old. Most of the fundamental techniques of biotechnology, systems analysis, and information science are of recent origin.

The technology development process must continue to consider *the incentives of final users.* Before new or existing techniques are adopted by an owner, manager, or consumer, many questions need answers. Will an alternative approach be more cost-effective? Can the farmer afford the additional cost when the prices of wheat, corn, or stumpage are so variable? What financial plan best fits a given farmer or household? The unique aspect of agriculture is the *extension educational process.* State specialists and county agents who interact regularly with the researchers also have the trust and understanding of producers and consumers. They take available research data from multiple sources and develop educational packages that consider the needs of users.

B. Basis for Needs Assessment Summary

In the Agriculture and Food Act of 1981, Congress reaffirmed the need for a publicly supported science and education system in agriculture (Title XIV, Section 1402). To meet future needs and challenges, the 1981 Act requires the development of a "Needs Assessment" that examines:

- the long-term needs for food, fiber, and forest products; and
- the supporting role of research, extension, and teaching programs.

This Congressional mandate provided a unique opportunity for the performers of science and education programs in agriculture to examine emerging problems and issues and communicate to both outsiders and themselves how these programs can help find solutions. Many influential people—in the Congress, in other branches of government, and in decisionmaking positions across the country—do not understand how the decentralized and pluralistic system of agricultural research and education works. This report is intended to demonstrate that dialogue does take place across and within administrative units and that the system does adjust to changing needs.

Initially, a 300-page "Reference Document" was completed—authored by 40 federal, state, and private-sector scientists, specialists, and administrators. A listing of the separate papers and authors is in Appendix B. The document highlights publicly supported research, extension, and higher education programs in agriculture. Interrelations with the private sector are often recognized. After a discussion of demand-supply projections, the document addresses problems and needed solutions in the areas of:

- natural resources—including soil, water, and air; forest, range, and wildlife; and energy.
- production agriculture—including crops and animals,
- processing, marketing, and distribution,
- agricultural policy—including adjustment concerns,
- families and communities—including human nutrition; consumer programs; and youth, family, and community development, and
- international activities.

57-279 O - 87 - 29

The report points out that in order to continue addressing the needs of U.S. agriculture, the science and education system must continually revitalize and update itself in the following areas:

- scientific expertise,
- biotechnology,
- information systems and communication technology,
- maintaining and improving the knowledge base, and
- equipment and facilities.

The "Reference Document" provided the basic material for this Summary. Other source documents included recent planning reports of federal and state performers. A list of these reports is in Appendix B.

This report obviously is not exhaustive in any sense toward covering all needs or technologies that bear on this major sector of the United States economy and its people. It does, however, serve to raise some of the major problems and opportunities envisaged for the future and presents the thoughts of some of the Nation's foremost scientists, educators, administrators, and agricultural leaders about technology and policies through which the science and education system can impact these problems.

II. Multiple Demands Facing U.S. Agriculture as the Nation Approaches the Year 2000 and Beyond

The primary function of U.S. agriculture is to provide food, fiber, and forest products for both domestic markets and an increasing share of international markets. But satisfying these product demands is only one dimension of today's agriculture. Natural resources must be properly managed so that future demands for agricultural products can also be satisfied; profitability of the farmer must be enhanced to insure a viable agriculture; efficiency of production must be improved—even more—so that all people can afford adequate food, clothing, and shelter; environmental quality concerns must be incorporated into production and processing technologies so that forests, waterways, and rural landscapes are pleasant places to live and enjoy; and the final consumers must be supplied with safe, high quality products that satisfy their changing needs.

All these demands must be addressed if the United States is to continue as a world leader in high-technology agriculture. Past improvements in land and labor productivity didn't just happen. Committed scientists and specialists were supported by producers and consumers of food, fiber, and forest products and they returned that support with improved technologies that we now take for granted. No industry can rest on its past successes. The recent experiences in the steel and auto industries should have taught us that hard lesson.

The following sections explore these needs and issues in more detail: projected needs for food, fiber, and forest products; sustaining and improving productivity; adequacy of the natural resource base and environmental concerns; and providing nutritious, safe, and high-quality products.

A. Projected Needs for Food, Fiber, and Forest Products

In recent decades the agricultural and forestry industries have become increasingly dependent upon international trade. Domestic demand for food, fiber, and timber products is expected to remain strong, but exports are expected to be the major force in determining future demand levels. World macroeconomic developments and monetary policies have had significant influence on the U.S. agricultural and forestry sectors. Thus such global variables as population growth and composition, income growth and distribution, inflation, exchange rates, interest rates, oil and other com-

modity prices, credit policies, technology, and institutional changes are important in assessing the demand for U.S. agricultural and forestry products. These factors will undoubtedly influence the future growth and development of farming and timber production patterns in the decades ahead.

Global Demand for Food and Fiber[1]

The forces and events that will determine the global demand for U.S. food and fiber through the end of the century cannot be predicted with a high degree of precision or certainty. However, the trends likely will depend on those already underway. Accordingly, the projections presented in this study rely heavily on an analysis of those factors that change slowly, follow fairly orderly patterns, and play major economic roles. A basic assumption is continued world peace, which is a precondition of trade growth.

Population growth constitutes the most important force propelling the world demand for food and fiber. For the world and for most regions, the rate of population growth is projected to slow. The world's population is, nevertheless, expected to be 39 percent larger in the year 2000 than it was in 1980. In absolute numbers, the expected 1.74 billion increase over the last two decades of the century is enormous—an average of 87 million persons per year. The importance of such an increase to food supplies is difficult to overstate.

The world produced 1.57 billion metric tons of cereals in 1980. To provide the same amount of grain per person as in 1980 to 1.74 billion additional consumers will require an additional 650 million tons (Table 2). Furthermore, the geographic incidence of population growth will continue to be extremely unequal: more than 93 percent of the growth will be in the six least developed regions, more than 25 percent in South Asia alone and 20 percent in sub-Saharan Africa. By 2000, only 19 percent of the world's people will live in the six most developed regions, a decline from 23 percent in 1980.

This study assumes rates of real *income growth* per capita that are, for most regions, somewhat lower than those experienced in the 1970's. Food consumption changes in response to income changes are estimated by means of income elasticities derived from historical experience, with appropriate allowances for recent trends.

Consumption, production, and trade are also influenced by *national policies* which are subject to gradual or, occasionally, abrupt changes. Moreover, even where policy changes have only slight effects on consumption or production, they tend to have a much greater proportional impact on trade. Therefore, changes in national policies are probably the most important element of uncertainty in any long-term trade projections.

[1]Unless otherwise indicated, the projections were based on a study conducted for USDA by Resources for the Future. A copy of their report appears in the Needs Assessment Reference Document.

The analysis and presentation of findings were done for 12 regions in the world. The regions are described in Appendix A.

Projections of World Demand: The dimensions of the changes in the per capita demand for agricultural products resulting from the projected rates of income growth are shown in Table 1. The demand for cereal grains and oilseeds includes indirect consumption in the form of livestock feed. The changes are relatively small, except for fairly rapid increases in per capita meat consumption in countries that are in the process of attaining middle-income status, e.g., Middle East, Centrally Planned Economies of Asia, and Latin America. Increases in per capita demand for grain and oilseed are projected to be less than those experienced in the 1970's.

Table 1.
World Per Capita Consumption

Products	1969-71	1978-80	Annual Change	2000	Annual Change
	kg/capita		percent	kg/capita	percent
Meat	28.3	31.8	1.3	36.8	0.70
Milk	108.0	107.1	−0.1	102.7	−0.21
Cereal Grains	334.7	361.0	0.8	371.7	0.14
Oilseeds	29.7	35.5	2.0	40.5	0.57
Fibers	5.3	5.0	−0.6	4.9	0.1

The increases in aggregate demand are, nevertheless, very large when population growth is taken into account (Table 2). World demand for meat is projected to increase by 89 million tons, or 64 percent; for milk, by 168 million tons, or 36 percent; for grains, by 722 million tons, or 46 percent; for oilseeds, by 95 million tons, or 62 percent. The largest percentage increases tend to be in the developing countries. Thus, aggregate demand for meat is projected to double or more in North Africa/Middle East, South Asia, East Asia, Centrally Planned Economies of Asia, and Latin American regions; the demand for dairy products will almost double in North Africa/Middle East, South Asia, Centrally Planned Economies of Asia, and Latin America. The increased demand for livestock products will contribute significantly to the growth of aggregate demand for cereals and oilseeds, over and above the increased demand for grains and oils for direct human consumption.

Table 2.
Anticipated Growth in Aggregate Demand
(In Millions of Metric Tons)

Region[1]	Meat			Milk			Cereals			Oilseed			Fiber		
	1979-80	2000	Increase	1979-80	2000	Increase	1979-80	2000	Increase	1979-80	2000	Increase	1979-80	2000	Increase

[1]Countries included in regions are shown in Appendix A.

Production and trade projections for each region of the world are available in the Needs Assessment Reference Document. They represent the best judgment of what is likely to happen under present or only slightly modified policies. They take into account considerations of comparative advantage and consumer welfare that favor increased trade, but also foreign exchange constraints and self-sufficiency and farm income objectives that may work in the opposite direction.

Source of Uncertainties: All projections of this kind are subject to uncertainties at every step in the analysis. Some examples follow:

For several decades following World War II, there was a tendency to underestimate future *population growth*, mainly because forecasters did not fully foresee the effects of progress in medicine and sanitation in reducing mortality in the developing world. More recently, the tendency has been to overestimate future population growth because of a lag in recognizing the decline in fertility rates in the wake of urbanization and industrialization, more widespread education and family planning programs, and the gradual enhancement of the social status of women. Even small revisions of population growth rates can have significant effects on the food projections.

As with population, analysts often have to work with evidence that is out of date. Therefore, they are slow to recognize changes that have already taken place, let alone changes that are likely to occur in the period of projection. Moreover, past *income growth* may have delayed effects in the future because it may take years, even a generation, for national diets to adjust to higher levels of affluence. Although an effort has been made to allow for ongoing changes, it is possible that the income elasticities for livestock products are still too low for some rapidly developing regions and too high for some affluent regions where demand is approaching satiation. For example, if per capita income growth were one-half of 1 percent higher than the base-line projections, the world demand for meat would be 8.6 percent greater and world trade in meat 42 percent greater. The effect on grain trade would not be as large (6.0 percent).

Trade patterns are highly sensitive to changes in *competitive conditions*. The United States has a substantial comparative advantage in grain and soybean production, but other countries—including Canada, Australia, Argentina, and Brazil—have become major competitors. The United States is not a significant exporter of livestock products and is not likely to become one, but it is conceivable that competitive conditions could become more favorable.

Agricultural production, consumption, and especially trade are strongly influenced by *national food and agricultural policies*. This is equally true of the centrally planned and market economies in both the developing countries and the developed world. Virtually all governments intervene extensively in agricultural markets by means of regulation, subsidization, or protection. Changes in these policies are undoubtedly the most important source of uncertainty in any long-term agricultural projections.

Implications for the United States: The United States, since the late 1960's, has pursued an agricultural policy for grains, oilseeds, and cotton that is geared to the world market. As domestic demand leveled off, production has responded primarily to trends and fluctuations in export demand. The sharp rise in export volume in the 1970's was attained by increasing acreage and yields, without lasting effects on real prices. The more moderate growth in exports projected for the next two decades is likely to come mainly from increased productivity per acre and per unit of input.

Total aggregate domestic demand for cereals is projected to increase by 18 percent, from 192.7 million metric tons in 1979-81 to 227 million tons by the year 2000. Similar increases are projected for oilseeds (22 percent), meat (19 percent) and milk (21 percent).

Net U.S. exports of cereals are projected to increase from 110 million metric tons in 1979-81 to 168 million metric tons at the end of the century. The grain export volume thus would increase by only 53 percent in 20 years, compared with the tripling experienced in the last decade. Oilseed exports are projected to increase from 33 million metric tons in 1979-81 to 54 million tons in 2000, roughly a 64 percent increase in 20 years compared with the doubling observed in the 1970's. For meat, the United States is projected to be essentially self-sufficient, with exports offsetting imports. For dairy products, net imports are projected to continue at less than 1 percent of domestic consumption (Table 3).

Table 3.
Historical and Projected Demand for Major Agricultural Products, U.S.

(In millions of metric tons)

	1969-71			1979-81			2000		
Commodity	Domestic[a]	Net Trade	Total	Domestic[a]	Net Trade	Total	Domestic[a]	Net Trade	Total
Cereals	171.0	39.0(19%)	210.0	192.7	109.6(36%)	302.3	227.0	168.2(42%)	395.3
Oilseeds[b]	20.2	17.0(46%)	37.2	31.5	33.3(51%)	64.8	38.1	53.9(59%)	92.0
Meat	21.9	.6(2%)	21.2	24.5	0 (0)	24.5	29.2	0.1(0)	29.3
Milk	53.4	-.2(-.4%)	53.2	59.0	-0.8(-1%)	58.2	71.1	-0.9(-1%)	70.2
Cotton	1.71	0.5(23%)	2.22	1.5	1.54(51%)	3.01	1.4	2.2(60%)	3.6

[a]Includes food, feed, seed, industrial use and waste
[b]Includes oilseed trade, in oilseed equivalent
Figures in parenthesis show net trade as percent of total use.

U.S. Policy: The base-line projections for the United States presuppose no major changes in policies that would significantly affect the long-term trends. It is assumed that the United States will stand ready to meet, at competitive prices, any increase in demand for its agricultural exports; and that there will be no attempt to raise the average level of export prices of these commodities above competitive levels, either unilaterally or in concert with other exporters. (This does not exclude the adoption of more effective domestic and international measures aimed at reducing year-to-year fluctuations). Import protection for dairy products and beef is assumed to continue at present levels.

Significant departures from these policies could change the trade patterns. For example, unilateral attempts by the United States to nudge export prices into higher territory could be expected to stimulate production abroad and reduce the U.S. market share. It would also adversely affect total demand, especially in low-income countries, and encourage the use of substitutes. On the other hand, policies aimed at accelerating the growth of productivity would tend to improve the competitive position of U.S. agriculture.

With no major changes in U.S. food and agriculture, monetary, and fiscal policies, U.S. export prices will continue to be volatile—very high at times and very low at times. The U.S. market share will rise when supplies are relatively tight and decline when they are relatively abundant.

Global Demand for Forestry Products

Of the 11 billion acres of forest lands that exist in the world, roughly one-third is commercially valuable and in use, one-third is unlikely to become commercially valuable, and the remaining one-third is potentially commercial but may not be in use or is inaccessible at this time.

Slightly more than half the world's forest areas are deemed accessible by existing roads, railways, waterways, or other transportation. Nearly all forests in Europe are accessible and in use, but other regions have large tracts of inaccessible forests, particularly the Amazon Basin and the northern parts of the Soviet Union and North America.

The volume of growing stock in forests in use is estimated at 5.5 trillion cubic feet—two-thirds coniferous and one-third broadleaf. Broadleaf (hardwood) species predominate, but more than half of the forest area in use is coniferous. The Soviet Union, Europe, and North America, with less than one-third of the world's population, have two-thirds of all forests, containing 90 percent of the coniferous area in use. The three areas account for two-thirds of all removals, including more than 80 percent of the world's output of industrial roundwood.

The growth of world consumption over the past 25 years for the three principal categories of forest products—lumber, wood panels, and paper—is given in the following tabulation:

	Annual Percent Growth in Consumption		
	Lumber	Panels	Paper
Developed Countries	1.1	6.2	3.8
Developing Countries	4.1	10.9	7.2
World	2.0	8.0	5.0

The United Nations Food and Agriculture Organization (FAO) projects that world demand for industrial roundwood will grow by about 2 percent per year for the next 20 years. According to FAO, consumption of paper and paperboard is expected to increase by 75 percent, wood-based panels by 55 percent, and lumber by 25 percent between 1980 and 2000. Although the absolute quantity of these projections can be questioned, they do point out prospects for growth in world forest products consumption. Net exports of logs and wood products are expected to increase by about 50 percent by century-end, with the main importers continuing to be Japan and Western Europe. The primary exporters are expected to be North America, USSR, and Southeast Asia.

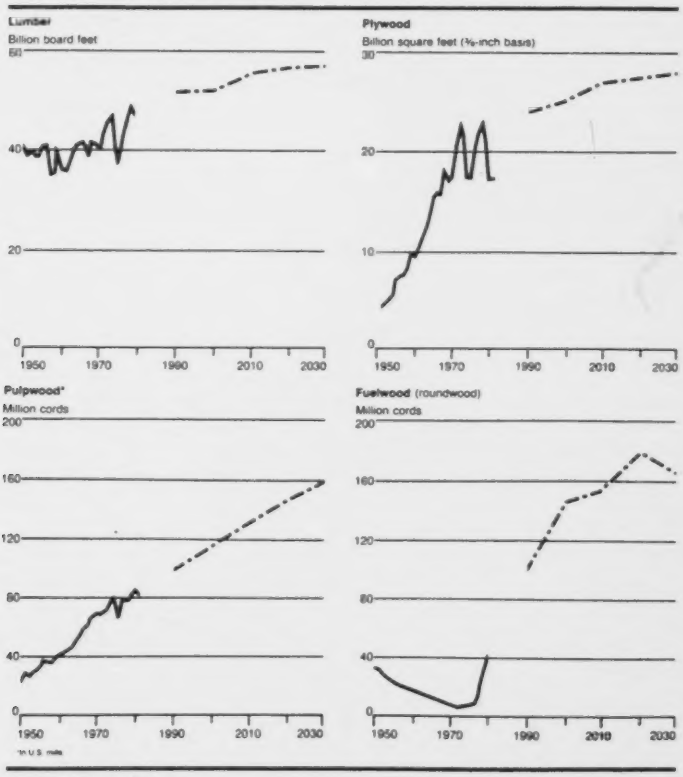
Implications for the United States:[3] Beginning with settlement and for a long time after, timber was the Nation's most important raw material. It had wide use in all types of construction and manufacturing, ranging from houses, bridges, and even road surfaces to the wagons and ships which provided the chief means of transportation. It was also the main source of fuel for domestic and industrial uses. Although over the years domestic and industrial users turned more and more to masonry, iron, steel, plastics, and other raw materials, and to fuel oil, gas, and other nonwood materials for power and heating, the demand for timber products continues, and, in total, has been rising.

Between 1950 and 1980, there was no well-defined trend in lumber consumption (fig. 1). Pulpwood use, however, increased nearly three times and plywood use more than four times. Since 1980 the recession has caused a substantial drop in consumption of lumber and plywood. The use of roundwood for fuel followed a long downward trend through the mid-1970's. Since then, consumption has increased rapidly in response to rising costs of oil and natural gas. Fuel use in 1980 was five times that of 1976.

[3]Supplement to the 1979 assessment of the Forest Rangeland Situation in the United States, U.S. Forest Service, November 1983.

As illustrated in figure 1, the longrun demands for all major timber products are projected to go up over the next five decades; as in the past, the demands for some products rise more rapidly than for others. Roundwood fuel demand rises at first and then after 2010 begins to decline, a response to projected increases in stumpage prices and fuelwood costs.

Figure 1.
Projected Timber Product Demands



Source: U.S. Forest Service

These timber product demands are met by softwood and hardwood logs. By the year 2000, softwood demand is expected to increase by 20 percent. This is in response to an expected surge in homebuilding in the last half of the 1980's as the large numbers of people born during the 1950's and 1960's seek their own place to live. Pent-up demands resulting from the recent low levels of housing construction will also contribute to the increase in housing construction.

Projected demand for hardwood timber is expected to increase 52 percent by 2000. This is largely due to growth in demands for pulpwood, fuelwood, and products such as pallets, railroad ties, and furniture.

In 1982 the United States imported about the same volume of wood products as it exported. Imports amounted to $8.4 billion; exports were $7.2 billion. During years of higher wood product consumption, the United States has been importing about twice as much as it exports. In 1979, for example, 3 billion cubic feet of timber products were imported and 1.5 billion cubic feet were exported. This trade imbalance is expected to continue into the future unless the United States becomes more competitive in world markets. According to a 1983 report by the Office of Technology Assessment:

> "The United States has an unprecedented opportunity to expand its exports of many forest products. There are three principal reasons for this: 1) world demand for paper and solid wood products is expected to grow rapidly, 2) many established wood-producing nations are confronted with diminishing wood supplies, and 3) the United States has both an abundant wood resource and a highly developed manufacturing capacity compared with most other countries."

In response to the 1980 Resource Planning Act documents of the Forest Service, Congress has recommended that the United States become a net exporter of timber products by the year 2000.

B. Sustaining and Improving Productivity[4]

"The capacity to develop and to manage technology in a manner consistent with a nation's physical and cultural endowments is the single most important variable accounting for differences in agricultural productivity among nations" (Ruttan, 1982).

[4]This section is based on an article written by W. Burt Sundquist, University of Minnesota, for "The Farm and Food System in Transition", a Cooperative Extension Project (1983).

As Ruttan's statement implies, technology policies for the agricultural system are of crucial importance if the system is to be productive. Past U.S. policies have had a substantial degree of success. For example, the cumulative effect of growth in agricultural productivity since 1940 added an estimated $112 billion to national income in 1979 alone. On the negative side, there have been recognized adverse effects (economic, environmental, and human) from some technologies. But regardless of past successes (and problems), the sources, types, and impacts of new technologies are changing and policies need to change also.

Most of the pre-20th century increase in United States farm production came from expanding the agricultural land base. This changed, however, in the decades which followed the closing of the land frontier. By the 1950's and 1960's most of the production gain came from increased productivity (an increase in the ratio of output to input) resulting from the use of science and technology. This gain came primarily from three sources: labor-saving mechanization, agricultural chemicals (particularly fertilizers, pesticides, and feed additives), and modifications in biological systems (particularly through the use of improved crop varieties and animal breeds). Much of this new technology had its origin in public research and was developed and delivered in product form through the private-sector supply industry.

But the current labor input in crop farming is small (5 percent or less of total costs for major field crops). It is somewhat higher, but declining, for animal products and for most specialty crops. Therefore, mechanization technology probably cannot greatly increase labor productivity in the future, but it can make contributions in other ways. The same applies to agricultural chemicals. Thus, *there is a crucial need to identify technologies with future productivity potential in farming and to institute policies which will help to realize this potential.*

Other factors also need to be considered in developing future policies. One consideration is that the benefits of technological change and increased productivity from mechanization, while reducing production costs for farm operators, normally mean job displacement for some farm workers. Moreover, most gains in labor productivity come at the expense of increased capital inputs. As a result, some farm operators are suffering from high capital investments which have resulted in serious cash flow problems for them. Other operators, unable or unwilling to make large capital investments, have ceased farming or now manage "low-income" farm units.

In addition, some new production technologies have generated environmental problems (such as soil erosion and toxic pollutants) which need to be considered. Thus there are important "trade-offs" to consider in developing future agricultural technologies that improve productivity.

Technology has also changed greatly in those segments of the agricultural system which lie beyond the farm gate. Since World War II this "post-harvest" or "processing

and distribution" sector has grown steadily in importance. Processing and distribution costs now account for over 70 percent of the current retail price for a consumer's market basket of farm products. The major marketing sector components of the system are farm commodity markets, transportation, processing, wholesaling, and retailing. Clearly, technology and productivity policies are important in these post-harvest components of the system too.

Productivity and Technology Defined

When a society's resources are being fully utilized, the real income status of both producers and consumers can be improved only through productivity gains—this is true both in periods of commodity surpluses and in periods of shortages. Yet one source of uncertainty about what constitutes appropriate productivity and technology policies is confusion about the meaning and use of the term "productivity." When the term productivity is used accurately, it always refers to the ratio of output to input. For example, *total productivity* is the ratio of output per unit of total input. In this measure the several inputs used in the production of goods and services—land, labor, buildings and equipment, energy, and other—are value-weighted and aggregated so that changes in output can be related to changes in total input. If such a total productivity measure is constructed carefully, it can be interpreted as a reasonably accurate depicter of technical efficiency and used to measure changes in efficiency over time.

Partial productivity measures, on the other hand, relate a selected input or group of inputs to output. Labor and land productivity measures are probably the most commonly used partial productivity measures for the agricultural system. But they have serious potential hazards: gains in labor and/or land productivities, for example, can be offset by increased capital requirements, leaving total productivity (or technical efficiency) unchanged or even reduced. Thus, total productivity is preferred to partial productivity as a measure of technical efficiency, and care should be used in interpreting the results of any partial productivity measure. *Even the total productivity measure, however, does not include such factors as environmental, social, or structural impacts of technologies.* So technology evaluation cannot be limited only to productivity measures.

The term technology is generally meant to imply a specific state of art and science which is used to transform a set of inputs (resources) into a set of outputs (goods or services). Thus the Nation's agricultural system uses a large number of technologies to produce, process, and distribute food, fiber, and forest products. Technical changes can be said to occur when the form or mix of either inputs or outputs are modified from their previous state. Thus, for example, the change from use of animal power to tractor power in production agriculture constituted a major technical change. So did the shift in forestry from hand saws to chain saws for harvesting trees. Though it is common to do so, no superiority should be automatically granted to a technology just because it possesses a single attribute such as efficiency or environmental cleanliness. Some attributes are, of course, more important than others, and technical efficiency is virtually always very important.

The significance of technical change is that it permits the substitution of knowledge for resources, or of inexpensive and abundant resources for scarce and expensive resources, or that it releases the constraints on growth imposed by inelastic resource supplies. In the process, this change generally provides some economic benefits by a cost-reducing "productivity dividend." While a change in technology can be scale-neutral, adoption of most new technologies results in increased volume capacities for the adopting firms. As a result, fewer firms are needed in the system. In addition, most recent new technologies have resulted in increased capital inputs per unit of output. And many, if not most, new technologies have been induced by cheap (undervalued) fossil-source energy inputs. Finally, the trend toward greater reliance on science-based discoveries in the development of new technologies—the so-called fusion of technology and science—has been pervasive in agriculture and is expected to continue and even to accelerate in the future.

C. Adequacy of the Natural Resource Base and Environmental Concerns

The adequacy of the U.S. natural resource base to sustain continued expansion of agricultural and forestry production came under increasingly intense scrutiny during the 1970's as a result of several events. High rates of growth in exports resulted in the return to production of some 60 million acres of cropland held in reserve under government programs in the late 1960's. With the incentive of high commodity prices in the mid-1970's, and expectations of low-cost capital, planted cropland expanded to a record high 390 million acres in 1981. The emergence of large stocks of grain in 1981 and 1982 and the withdrawal of nearly 83 million acres from production in 1983 muted but did not eliminate public concern about the adequacy and quality of the natural resource base.

At the same time, disquieting evidence of soil erosion, pollution of water supplies, overdrafts in water use in some regions, and mounting concerns regarding the environmental impacts of high usage of chemicals raised serious questions about the long-run consequences of continued high rates of growth of "high-tech" agriculture and forestry. Expectations of a slowdown in agricultural productivity growth rates were additional sources of concern.

The specter of impending crises in the availability of land and water resources to sustain growth in agricultural and forestry production evolves in part from preoccupation with the fixed physical nature of those resource supplies. But the demand for and use of those resources are determined by human choice and are powerfully influenced by social and economic criteria. Scarce resources are socially valuable resources. As a resource becomes scarcer and more socially valuable, users conserve it by substituting other resources and by adopting resource-saving technologies and management practices. Economic scarcity of a resource tends to induce an increased supply of compensating technologies. This principle of substitution is dramatically evident in the performance of U.S. agriculture and forestry in recent decades and is likely to be even more the case in the future.

Several complex, sometimes countervailing, forces will shape the competition for natural resources into the 21st century. In an increasingly interdependent society, it is to be expected that competition for natural resources will heighten. In general, the value of both water and land in nonagricultural uses exceeds their value in agriculture. Thus, where markets are operating freely and efficiently, agriculture in many locations will be in a weak competitive position for use of those resources in the 21st century. Somewhat related is the likelihood of continued erosion of the political power of agricultural interests at the national level and in many states. By the 21st century, agricultural policymakers will find it increasingly difficult to obtain or even maintain "special interest" policies for water, other resources, or agricultural commodities.

Soil Resources: A comprehensive report by Crosson and Brubaker (1982) speculates on the resource and environmental effects of U.S. agriculture to the year 2010. Anticipating greater use of herbicides to complement expanded conservation tillage, they point to gaps in knowledge about the long-term effects of even present application rates. However, they conclude that the major threat to the Nation's environment is that of soil erosion through its effects on water quality and potential productivity losses on agricultural cropland. A recent national workshop sponsored by 10 scientific societies cited "sustainable soil productivity" as their first research objective (Soil Science Society of America, 1981). Larson (1983) reports that in 1977, sheet and rill erosion exceeded "T" values (the maximum level of soil erosion that will permit a high level of crop productivity to be maintained economically and indefinitely) on some 113 million acres of cropland (27 percent of the total); on 10 percent of the cropland, erosion was more than double "T" values.

Land Resources: During the next three decades, economic pressure from nonagricultural demand on the agricultural and forest land base should be less than it has been during the past 30 years. This pressure resulted in an average annual net transfer from agriculture of some 3 million acres (875,000 acres from cropland, actual or potential) in the period 1967-75.

U.S. population growth rates are slowing. Depending upon costs of energy and social services, the dramatic migration from metropolitan to nonmetropolitan areas in the 1970's should slow. Construction rates for new airports, water and highway transport systems, dams, and reservoirs—all significant claimants upon cropland in the past—have already slowed. There are, of course, important regional and local exceptions to such generalizations. In the "sunbelt" states, for example, competition for land will intensify, posing critical choices among agricultural, urban, industrial, and other enterprises.

Water Availability: The availability and price of water, rather than land, appears to be the more critical natural resource variable for agriculture through the remainder of the century, particularly in the West. In the absence of subsidized large interbasin water transfer, it seems clear that water will be increasingly costly in the southern Great Plains with the possible result of forcing changes in water management on substantial amounts of irrigated land. Transfer of water from agriculture to meet demands in growing urban centers in the West and Southwest, whether through the expanding markets for water rights or through other institutional arrangements, could induce major adjustments in agriculture in those areas. And it seems evident that there will be no large-scale federal investment in the next decade or two in water development projects. Public policy for water in the West is moving from that of development of additional supply to that of managing the increasingly more valuable current supply.

Water Quality: Beyond these physical and economic dimensions of water resources are major problems of water quality. Groundwater contamination from agricultural as well as nonagricultural sources has become a serious problem in many parts of the country. Irrigation practices in the West have increased groundwater salinity. "Perhaps one-quarter of the lands currently under irrigation in the West are heavily dependent on nonrenewable water supplies, and the productivity of several million additional acres is threatened by rising salt levels" (Frederick, 1980). Pesticides and fertilizers may eventually seep into groundwater.

Other water quality problems—dissolved oxygen; suspended solids carrying bacteria, nutrients, and pesticides; excessive phosphoric and nitrogenic nutrients—derive in part from agricultural production practices. The 1972 Federal Water Pollution Control Act set forth ambitious goals to improve water quality. Although progress has been made—scattered evidence suggests that some of the worst pollution problems may be abating—much remains to be accomplished. Water management and water policy of the future must be concerned not only with an increasingly scarce economic resource but with externalities which affect water and environmental quality. Maintaining or improving water and environmental quality may require modification of agricultural production practices and ultimately result in higher direct costs of agricultural production (Christensen, 1983).

Energy Availability: With respect to future prices of off-farm production inputs, the future price of energy is perhaps most critical. Although the agricultural sector adjusted fairly readily to the sharp increases in petroleum and other fossil-fuel-dependent inputs such as nitrogen fertilizer in the middle and late 1970's, it did so under conditions of generally rising farm product prices. Although current expectations suggest only small increases in the real price of fossil fuel energy for the remainder of this decade and possibly to the year 2000, the tenuous, volatile international political circumstances of world petroleum supplies and prices remain a source of substantial uncertainty for much of of the U.S. economy. This suggests the importance of developing non-petroleum energy sources, energy-conserving technologies and production systems, and energy policies which provide incentives for conservation.

D. Providing Nutritious, Safe, and High-Quality Products

American consumers have access to more high-quality, moderately priced, safe food, fiber, and forest products than any other people in the world. This results from a complex but very successful interaction of private and public sectors. The research, education, and regulatory functions of governmental agencies and the technical and managerial expertise of industry form a partnership that means better food, clothing, and shelter for all.

Food: We know a great deal about human nutrient needs, but we must learn more. As new crop varieties and livestock strains are developed through improved breeding techniques, including genetic engineering, changes in the nutrient composition of food may be introduced. Improved food processing techniques to reduce costs, increase storage time, and produce new foods may also have unforeseen effects on the nutrient content of food.

The U.S. population is growing older. By the year 2000 the U.S. is expected to have over 30 million people 65 years of age and older. As many as one in five will be in that age category during the 21st century. Nutrient needs, food choices, and the ability to digest and absorb food are likely to change with age. For example, some have suggested that our older population will need more protein and calcium in their diet. Will it be best for older people to choose meat and milk to meet these needs? Would other food choices be better to increase chances of remaining in good health? Can proper nutrition delay or prevent heart disease, cancer, osteoporosis, and other diseases of old age? There are many questions needing answers.

Regulatory agencies like the Food Safety and Inspection Service (FSIS) are becoming more dependent on a technical information base to make and carry out their decisions. The problems that FSIS addresses involves questions of safety such as toxicities, residues, nitrites, and microbial contaminations and questions of quality such as appropriate food additives, ingredients, and processing and grading specifications.

Wood and Fiber: The wood and fiber industries are not as highly regulated as the food industry is, but these products must undergo several safety and quality checks before they reach the consumer. Voluntary compliance with industry-wide codes is a dominant feature of these sectors. Major buyers of lumber, cotton, and wool also have considerable impact on the type of products that are made available to the consumer. For example, public and private financial institutions specify the type of materials and construction standards for structures they finance. Publicly supported science and education programs are a major source of technical data and analysis.

The foundation on which standards are established for processing and grading cotton, wool, and wood products is government-sponsored research. The results have the credibility required to establish industry-wide compliance. A few examples of problems requiring answers now are: 1) Identifying the agent causing brown lung disease—a disease associated with employees exposed to cotton dust; 2) Improving techniques for measuring strength and length of cotton and wool fibers; 3) Improving design of

wood structures—it has been estimated that improved engineering and construction practices could save 10 to 20 percent of the dimensional lumber required in a conventional house with no loss in performance.

III. How Science and Education Can Help U.S. Agriculture Meet Changing Demands

Many variables associated with agricultural production can alter output levels. These variables include: the condition and supply of natural resources; weather; government policies; competitive position; environmental goals; and technology. The impacts of these variables are interrelated, not mutually exclusive.

Most of the increases in crop and forest yields needed by the year 2000 will come from existing or emerging technologies. Improving the Nation's competitive position will require a more efficient use of land, water, and purchased inputs such as fertilizers, herbicides, and energy. Increased production can occur without depleting our soil and water resource base if appropriate conservation practices and economic incentives can be more closely intertwined. Establishing realistic environmental goals requires a sharing of ideas between the urban consuming public and producers as well as the incorporation of environmental concerns into new technologies. Government policies are largely established in the political realm, but can be heavily influenced by careful analysis that considers economic, social, and biological consequences of alternate policies. While the weather cannot be altered at the present time, there are many realistic strategies that can be used to reduce the adverse effects of weather on agricultural production.

These variables are discussed in more detail below. For each of six broad subject categories—natural resources; production agriculture; processing, marketing, and distribution; agricultural policy; family and communities; and international activities—problems and issues are discussed where science and education can help find answers. The emphasis is on the role of science and education, but there is an awareness that new ideas are not adopted in a vacuum. Before a farmer, processor, or consumer will adopt a better approach, there must be motivating incentives like higher economic returns. Before alternative policies are considered by policymakers, they must adhere to political persuasions of elected officials.

Science programs of the future will include two common features—systems analysis and economic feasibility studies. Scientists will integrate data from basic and applied research into models that simulate agricultural activities and practices. Then, by the process of systems analysis, they will compare the effectiveness of alternate strategies before testing and validating the results in a field experiment. Economic feasibility studies should increase effectiveness of research investigations and extension programs and provide needed information for potential users of new or existing technologies. The development of microcomputers and associated telecommunication systems enhances the use of these techniques. These two features apply to most of the following categories.

A. Natural Resources

Much can be said about the importance of natural resources in the modern world. People look to land and water for the food they eat, for the fibers and other materials needed to clothe their bodies and to provide housing and manufactured goods, for building sites, for recreation opportunities, and for scenery and open space.

Average Americans often take their relationship to the natural environment for granted. Urbanization has separated the great bulk of the Nation's population from intimate contact with land and water as a producer of food, fiber, and forest products. Technological advance has removed the threat of famine and inadequate shelter, and comparative affluence has centered the concerns of most people on issues only indirectly related to their natural surroundings. Except for expressions of concern over the quality of the environment, most people now tend to view land and water resources as dependable and thus a routine input into their scheme of values. The fact that these resources are made more productive by capital investment and the addition of chemical and energy inputs does not mean that they are expendable or unimportant. In fact, their importance in absolute terms grows steadily with each passing year (Barlowe, 1972).

Soil, Water, and Weather

The 1977 Natural Resources Inventory shows that 38 percent of the U.S. cropland eroded at rates greater than that of soil formation by natural processes. Twenty percent eroded at twice this rate or greater. Sheet, rill, and wind erosion is considered excessive on 106 million acres of rangeland, 32 million acres of forest land, and 20 million acres of pastureland. Soil erosion pollutes lakes, streams, and estuaries and invokes regulatory actions by governmental units.

Some people argue that general yield-enhancing technological progress such as new plant varieties and improved agricultural chemicals will offset the effect of topsoil erosion on crop yields. Indeed, wheat yields have roughly doubled in the southeastern Washington Palouse area over the past five decades, despite continuous high levels of topsoil erosion. However, this observation does not tell the complete story. When topsoil depth is high (15 to 25 inches), loss of soil has little impact on per acre output. When topsoil depth is low (5 inches or less), the effect on per acre yield can be significant. Furthermore, the genetic yield potential of improved varieties will be restricted at the outset if poor seedbed conditions on compact clay subsoils reduce stand establishment (Walker and Young, 1983).

Soil Technology: Conservation tillage is the most significant technology being developed for producing crops and simultaneously controlling soil erosion. Reduced-tillage and no-till systems can maximize the crop residue cover on the land and conserve energy, labor, water, soil, fertilizer, and organic matter on the main food-producing areas of the earth (Wittwer, 1982). The highest priority extension activity requested by the Soil Conservation Service in 1983 was: "To accelerate extension efforts relating to conservation tillage".

However, there are still many obstacles to expanding the use of this technology. Crop residue remaining after conservation tillage acts as a mulch on the colder and wetter soils of the corn- and soybean-producing regions. This residue slows the warming and drying process in spring, sometimes delaying planting. Without plowing, some soils are vulnerable to compaction by vehicle traffic. To remove these obstacles, and others, continued research is needed on weed and pest control, tillage machinery, and alternative systems of tillage and fertilization practices.

Improved conservation practices, in addition to conservation tillage, are needed for water erosion control on steeper slopes. Historically, forage-based rotations, strip cropping, and terracing have been relied upon. Terracing, while effective in reducing erosion, has not been well accepted by farmers. In many cases, terracing is not compatible with the use of large machinery, particularly on complex topography.

An area of special concern in soil resource management is the lack of quantitative knowledge about the amount and quality of the Nation's soil resources. Without quantitative knowledge about soil degradation, including the costs of soil erosion, the extent and severity of soil compaction, or the importance of adequate drainage, policymakers are handicapped in creating effective conservation programs, action agencies cannot target their resources, and farmers continue to use conventional management practices. There are approximately 10,000 different soils in the United States, and each region and area has specific problems.

Water Management: As discussed by Boyer (1982), crop production is limited more often by water than any other production variable. Approximately 60 percent of the soils in the United States have capability limits related to deficient or excess water and nearly 60 percent of the crop loss indemnities paid to farmers are water-related. Production losses from the drought of 1980 were estimated at $20 billion. In the future, the acreage of water-stressed crops will increase because of increasing competition from other water users, declining groundwater levels in many areas, and increasing use of droughty or poorly drained soils.

Considerable progress has been made in irrigation scheduling for individual crops. Likewise, progress has been made in improving fallow efficiencies in northern areas. Other research and extension strategies for irrigated areas include increasing water-application efficiency, using irrigation return flows, and using water of impaired qual-

ity. Strategies for rain-fed agriculture include improving fallow and overwinter water-storage efficiencies, developing water-conserving tillage practices, managing snow and snowmelt, and harvesting water for run-on farming. Progress has been made in all these areas—but much more is possible. Considerable potential exists for improving the tolerance of crops to water stresses for both irrigated and dryland agriculture, but the mechanisms of tolerance need much more research. Drainage will be a continuing need for both irrigated and nonirrigated agriculture. Most subsurface drainage systems were designed and installed about 50 to 100 years ago. Many are inadequate today. In the humid and sub-humid regions, where supplemental irrigation will increase, combined irrigation-drainage systems will be needed. In regions where groundwaters are being depleted, a variety of research and extension programs will be needed to help made an orderly transition to less water-intensive technologies.

The regional diversity in the water supply and the demands placed upon it require similarly diverse educational programs to teach various audiences about the nature of such problems. Extension programs built upon appropriate research and technology should be designed to provide such knowledge so that citizens and governmental officials at the local and state levels will be able to make rational decisions regarding the problems and potential solutions.

Water Quality: As the use of land and water intensifies, water quality problems will become worse unless steps are taken now. The biological and economic effects of specific pollutants must be assessed in terms of subsequent water use so that rational standards can be established for maintaining the quality of water supplies. The Colorado River Basin is one of many examples. Salinity damages to agriculture and municipalities in that basin were estimated at $53 million in 1973, but are expected to reach $150 million annually by the year 2000 unless salt loading can be controlled.

Improved understanding of the factors affecting water quality will lead to the development of more accurate and reliable models that can be used to predict the effects of management practices on a farm, watershed, or river basin scale. In some cases, improved practices or combinations of practices will be needed. Research and extension programs on water quality should be coordinated closely with those on water management and conservation practices. The key to handling pollution concerns is to assess the major problem(s) in each area of the United States in terms of the actual or potential source of pollution and its effects, and then to develop the most appropriate responses. This will require continued close working relationships among Extension, Soil Conservation Service, Environmental Protection Agency, researchers, farmers, and others in the local areas.
